GRANIT: neutron
The Neutron

• 1930: Bothe and Becker in Germany bombard beryllium with alpha particles and observe a non-ionizing and penetrating radiation. Assumed to be gamma rays.

• 1932: Irène and Frédéric Joliot-Curie let the radiation hit a block of paraffin and observe that it caused the wax to emit protons. Interpret the protons as ejected by gammas.

• Rutherford and Chadwick do not think that gamma rays are responsible.

• 1932: Neutron discovered in experiment by Chadwick.

Neutron Decay

- 1934: Chadwick and Goldhaber detect the photo-disintegration of the deuteron ("diplon") in the reaction

\[ ^2H + \gamma \rightarrow ^1H + n + Q \]

From the \( Q \)-value, they determine an estimate for the neutron mass, which is \textit{greater} than the proton mass.

- The implication is that the neutron is energetically allowed to decay:

\[ n \rightarrow p + e^- + \bar{\nu}_e + 783 \text{ keV} \]

- 1948: Snell and Miller at Oak Ridge definitely observe the neutron decay into a proton (and Robson 1950 at Chalk River).

A collimated beam of neutrons, three inches in diameter, emerges from the nuclear reactor and passes axially through a thin-walled, aluminum, evacuated cylindrical tank. A transverse magnetic field behind the thin entrance window cleans the beam of secondary electrons. Inside the vacuum, axially arranged, an open-sided cylindrical electrode is held at +4000 volts with respect to ground. Opposite the open side a smoothed graphite plate is held at −4400 volts. The field between these electrodes accelerates and focuses protons which may result from decay of neutrons, so that they pass through a 2\(\frac{1}{4}\) × 1\(\frac{1}{8}\) inch aperture in the center of the graphite plate, and then strike the first dynode of a secondary electron multiplier. The second dynode is specially enlarged so as to cover the entire field in the neutron beam; (2) with and without a thin foil over the multiplier aperture; (3) with and without the accelerating voltage. In a total counting rate of about 300 per min., about 100 are sensitive to operations (1), (2), and (3). In the absence of the accelerating field or with the foil (2) in, operation (1) does not change the counting rate. Assuming all of the 100 c.p.m. to be due to decay protons, preliminary estimates of the collecting and counting efficiency (10 percent) and of the number of neutrons in the sample \(4 \times 10^4\) give for the neutron a half-life of about 30 minutes. It is at present much safer however to say that the neutron half-life must exceed 15 minutes. Coincidences are presently being sought between the disintegration betas and the collected protons.

Snell and Miller, Phys. Rev. 74, 1217A (1948)
Neutron Decay Parameters

- \((m_n + m_p)c^2 = 1877\text{ MeV}\); \((m_n - m_p)c^2 = 1293\text{ keV}\)

- Decay products: \(n \rightarrow p + e^- + \bar{\nu}_e;\) \(\tau_n \approx 15\text{ min.}\)

  \[0 < T_e < 782\text{ keV}\]

  \[0 < T_p < 751\text{ eV}\]

- Other decay modes:

  \(n \rightarrow p + e^- + \bar{\nu}_e + \gamma\) \(BR(15\text{ keV}) \approx 3 \times 10^{-3}\)

  \(n \rightarrow H^0 + \bar{\nu}_e\) \(BR \approx 4 \times 10^{-6}\)

BBN and Light Element Abundance

Thermal Equilibrium \( (T > 1 \text{ MeV}) \)
\[ p + \bar{v}_e \leftrightarrow n + e^+ \]
\[ n + v_e \leftrightarrow p + e^- \]
\[ \frac{n}{p} \sim e^{-Q/T} \]

After Freezeout
\[ \frac{n}{p} \text{ decreases due to neutron decay} \]
\[ n \rightarrow p + e^- + \bar{v}_e \]

Nucleosynthesis \( (T \sim 0.1 \text{ MeV}) \)
Light elements are formed.
\[ p + n \rightarrow d + \gamma \]
\[ d + d \rightarrow ^4\text{He} + \gamma \]
almost all neutrons present \( \rightarrow ^4\text{He} \)

Neutron lifetime dominates theoretical uncertainty in \(^4\text{He}\) abundance.

Light Element Abundance

\[ Y_P = \frac{2(n/p)}{1 + (n/p)} = 0.249 \pm 0.009 \]

\[ Y_P = 0.326 \pm 0.075 \text{ (68\% CL)} \]

WMAP + ACBAR + QUaD

Nuclear beta-decay can in general be formulated as an interaction involving many possible couplings:

- $C_S$ - Scalar
- $C_V$ - Vector
- $C_A$ - Axial-vector
- $C_T$ - Tensor
- $C_P$ - Pseudoscalar

These couplings can be real or imaginary, parity-violating or conserving. There are 20 possible couplings.
Nuclear Beta-Decay

- Nuclear beta-decay can in general be formulated as an interaction involving many possible couplings

  \[ C_S - \text{Scalar} \]
  \[ C_V - \text{Vector} \]
  \[ C_A - \text{Axial-vector} \]
  \[ C_T - \text{Tensor} \]
  \[ C_P - \text{Pseudoscalar} \]

- These couplings can be real or imaginary, parity-violating or conserving. There are 20 possible couplings.

- Experimentally, nuclear beta-decay has been very well-described by two, real couplings \( C_V \) and \( C_A \) in \( V-A \) theory.

- Experimentalists continue to test the validity of the theory - and search for hints of failure - through increasingly precise measurements of the decay observables.

Beta Decay Probability of a Free Neutron

One possible interaction
\[ M = \frac{G_F}{2\sqrt{2}} V_{ud} \bar{\psi}_p \gamma_\mu (f + g_{5\gamma}) \psi_n \bar{\psi}_e \gamma^\mu (1 + \gamma_5) \psi_\nu \]

calculate the transition probability
\[ W = \frac{1}{\tau} = \frac{2\pi}{\hbar} |\langle f | M | i \rangle|^2 \rho_f \]

\[ g_V \equiv G_F V_{ud} f(0) \quad g_A \equiv G_F V_{ud} g(0) \]

Express the lifetime \( \tau \) as
\[ \frac{1}{\tau} \propto f \xi \]

where \( f \) is a kinematic factor and
\[ \xi = g_V^2 |\langle 1 \rangle|^2 + g_A^2 |\langle \sigma \rangle|^2 \]

yields
\[ \tau = \frac{1}{f(1 + \delta_R)} \frac{K/\ln2}{(1 + \Delta V_R)(g_V^2 + 3g_A^2)} \]
\[ \tau = \frac{1}{f(1 + \delta_R)} \frac{K}{G_F^2 V_{ud}^2 (1 + \Delta_R^V)(1 + 3\lambda^2)} \]

where \( f(1 + \delta_R) = \text{statistical rate fct + rad. corrections} \)

\( (1 + \Delta_R^V) = \text{radiative corrections (nucleus independent)} \)

\[ \tau = \frac{4908.7 \pm 1.9}{|V_{ud}|^2 (1 + 3\lambda^2)} \]

Correlation Coefficients

Angular distribution of decay particles from a polarized nucleus

\[ W((J), E_e, \Omega_e, \Omega_\nu) \, dE_e \, d\Omega_e \, d\Omega_\nu = \frac{1}{(2\pi)^5} p_e E_e (E^0 - E_e)^2 \, dE_e \, d\Omega_e \, d\Omega_\nu \]

\[ \times \xi \left[ 1 + a \frac{p_e \cdot p_\nu}{E_e E_\nu} + b \frac{m_e}{E_e} + \frac{\langle J \rangle}{J} \cdot \left( A \frac{p_e}{E_e} + B \frac{p_\nu}{E_\nu} + D \frac{p_e \times p_\nu}{E_e E_\nu} \right) \right] \]

Decay of polarized nuclei and its correlations with the electron momentum and polarization \( \sigma \)

\[ W((J), \sigma, E_e, \Omega_e) \, dE_e \, d\Omega_e = \frac{1}{(2\pi)^4} p_e E_e (E^0 - E_e)^2 \, dE_e \, d\Omega_e \]

\[ \times \xi \left[ 1 + \sigma \cdot \left( N \frac{\langle J \rangle}{J} + R \frac{\langle J \rangle}{J} \times \frac{p_e}{E_e} + \cdots \right) + \cdots \right] \]

Experimental Test of Parity Conservation in Beta Decay

C. S. Wu, Columbia University, New York, New York
AND
E. Ambler, R. W. Hayward, D. D. Hoppe, and R. P. Hudson,
National Bureau of Standards, Washington, D. C.
(Received January 15, 1957)

In a recent paper on the question of parity in weak interactions, Lee and Yang critically surveyed the experimental information concerning this question and reached the conclusion that there is no existing evidence either to support or to refute parity conservation in weak interactions. They proposed a number of experiments on beta decays and hyperon and meson decays which would provide the necessary evidence for parity conservation or nonconservation. In beta decay, one could measure the angular distribution of the electrons coming from beta decays of polarized nuclei. If an asymmetry in the distribution between $\theta$ and $180^\circ - \theta$ (where $\theta$ is the angle between the orientation of the parent nuclei and the momentum of the electrons) is observed, it provides unequivocal proof that parity is not conserved in beta decay. This asymmetry effect has been observed in the case of oriented Co$^{60}$.

It has been known for some time that Co$^{60}$ nuclei can be polarized by the Rose-Gorter method in cerium magnesium (cobalt) nitrate, and the degree of polarization detected by measuring the anisotropy of the succeeding gamma rays. To apply this technique to the present problem, two major difficulties had to be over-

*Phys. Rev. 105, 1413 (1957)*
CKM Quark Mixing Matrix

- CKM matrix represents a rotation of the quark mass eigenstates to the weak eigenstates.

\[
\begin{pmatrix}
  d_w \\
  s_w \\
  b_w \\
\end{pmatrix}
= \begin{pmatrix}
  V_{ud} & V_{us} & V_{ub} \\
  V_{cd} & V_{cs} & V_{cb} \\
  V_{td} & V_{ts} & V_{tb} \\
\end{pmatrix}
\begin{pmatrix}
  d \\
  s \\
  b \\
\end{pmatrix}
\]

- Unitarity requires \( |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 \)

- \( |V_{ud}| \) obtained from:
  1. nuclear decays
  2. pion beta decay
  3. neutron beta decay

\[
|V_{ud}|^2 = \frac{2984.48 \pm 0.05}{ft(1 + RC)} \text{ s}
\]

\[
|V_{ud}|^2 = (0.9749 \pm 0.0026)^2 \left[ \frac{BR(\pi^+ \rightarrow e^+\nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]
\]

\[
|V_{ud}|^2 = \frac{4908.7 \pm 1.9}{\tau_n(1 + 3\lambda^2)} \text{ s}
\]

$|V_{ud}|_0 = 0.97425 \pm 0.00022$

Neutron decay: $|V_{ud}|_n = 0.9765 \pm 0.0018$

Pion decay: $|V_{ud}|_{\pi} = 0.9728 \pm 0.0030$
The Caveats ...

Lifetime

- Publication Year
- Cold neutron beam
- Ultracold neutrons

Prospects

• Superallowed nuclear decays have done a remarkable job testing $V_A$ theory and limiting additional interactions. The neutron system is not yet competitive, but it is closer than one might think.

\[ \frac{\sigma_T}{T} = 0.17\%, \quad \frac{\sigma_\lambda}{\lambda} = 0.20\%, \quad \text{and} \quad \frac{\sigma_{th.}}{th.} = 0.04\% \]

• Large uncertainties come from underestimated systematic effects; fundamental limitations are not apparent. Note PDG scaling factors of 1.9 and 2.7.
Experimentation with Slow Neutrons

- The lifetime is too long. For a typical cold beam, $10^{-6}$ decay in detector volume. One must deal with systematics over a 15 minute period.

- Neutrons activate. The destiny of almost all neutrons is to become a potential background event.

- Neutrons are hard to manipulate. One must cool them over many decades of energy before magnetic fields, gravity, and optical potentials become relevant.

- Decay antineutrino is unobservable, and decay proton has an endpoint energy of only 751 eV.

**Neutron Lifetime:** \( N = N_0 e^{-\lambda t} \)

1. “In beam” method:

\[- \frac{dN}{dt} = N \lambda \]

Register the decay products from a well-defined volume traversed by a neutron beam of well-determined fluence rate.

2. Neutron “bottles”:

\[ \frac{N_1}{N_2} = e^{-\lambda (t_1 - t_2)} \]

An ensemble of ultracold neutrons in confined gravitationally or materially. Measure the change in neutron population.

3. Measure the slope of exponential decay:

\[ \ln \left( \frac{N}{N_0} \right) = -\lambda t \]

Watch the decay product of an ensemble of neutrons as a function of time and measure the slope.

   4 - Institute Laue-Langevin
   5 - Technische Universität München
Method of “Gravitrap” Experiment

- Confine UCNs gravitationally in material “bottle” (low temperature fomblin oil).

- Storage lifetime as a function of UCN energy and temperature.

- For an ideal wall (step function potential):

  \[ \lambda_{st} = \lambda_n + \eta \gamma \]

  where \( \eta = -\text{Im}(V_F)/\text{Re}(V_F) \) = wall loss coefficient
  \( \gamma = \text{loss-weighted collision frequency} \)

- Use two traps to reduce systematics: measure \( \lambda_{st}^1, \lambda_{st}^2 \)
  calculate \( \gamma^1, \gamma^2 \)

- Extrapolate neutron lifetime as function of gamma.
Gravitrap UCN storage

1 – neutron guide from UCN Turbine;
2 – UCN inlet valve;
3 – beam distribution flap valve;
4 – aluminium foil (now removed);
5 – “dirty” vacuum volume;
6 – “clean” (UHV) vacuum volume;
7 – cooling coils;
8 – UCN storage trap;
9 – cryostat;
10 – mechanics for trap rotation;
11 – stepping motor;
12 – UCN detector;
13 – detector shielding;
14 – evaporator
Extrapolation

\[ \frac{1}{\tau_{\text{storage}}}, \text{s}^{-1} \]

\[ \tau_{\text{storage}}, \text{s} \]

\[ \begin{array}{c}
0 & 1,160 \times 10^{-3} \\
1 & 1,155 \times 10^{-3} \\
2 & 1,150 \times 10^{-3} \\
3 & 1,145 \times 10^{-3} \\
4 & 1,140 \times 10^{-3} \\
5 & 1,135 \times 10^{-3} \\
6 & 1,130 \times 10^{-3} \\
\end{array} \]

\[ \gamma, \text{s}^{-1} \]

world average \( \tau_n = 885.7(8) \text{s} \)

Radial Confinement (Prototype trap)

Axial Confinement (Prototype trap)
Apparatus
Prospects

- Current value $\tau = (831^{+58}_{-51}) \, s$

- Studies of systematics from previous measurement show they are tractable at approximately the 1 s level.

- Key components of the next generation experiment have been tested and are operational.

- Two test cooldowns below 4 K. Cooldown in progress for first data run.

Goal of a 1-2 s measurement

The Standard Model and Beyond: $V_{ud}$

- Together with $\tau_n$ and the muon lifetime, measurements of $g_A$ permit a nuclear structure independent extraction of CKM matrix element $V_{ud}$

- **Assuming $\tau$ available at 0.1s level, require $\delta A/A \sim 0.1\%$** to produce an uncertainty of $\pm 0.00022$ in $V_{ud}$, the current value from $0^+ \rightarrow 0^+$ decays
  - Cross-check with neutrons would provide valuable confirmation
  - Recent theoretical activity probing accuracy of nuclear structure corrections (no serious challenges at present)
    

- $V_{ud}$ critical input to unitarity test, one of the most stringent constraints on “chirality conserving” interactions such as V-A:
  - 11 TeV lower bound on BSM mass scales. Better than Z-pole!
  - Constrains universality of supersymmetric models
  - 2-3 TeV lower bound on generic $W^*$ from Kaluza-Klein theories

from A. Young
A General Measurement Strategy

$\beta$ directional distribution: $1 + P \frac{v}{c} A(E) \cos \theta$
(polarized neutrons)

Detector

Detector

Magnetic Field
(entrains decay products)

$A(E) \propto \frac{N_+ - N_-}{N_+ + N_-}$

We must determine $P$ (the average neutron polarization), $v$ and $E$
(the $\beta$ velocity and energy) and $\cos \theta$

$N_+, N_-, v$ and $E$: Signals from the detector arrays $\rightarrow$ singles backgrounds subtraction critical
$\cos \theta$: use magnetic fields to capture all decay products $\rightarrow \langle \cos \theta \rangle = \pm 1/2$ (with small corrections)
$P$: polarize UCN, limit depolarization and measure depolarized UCN fraction

from A. Young
\[ A \propto \frac{\sqrt{R} - 1}{\sqrt{R} + 1} \], where \( R = \frac{N_{1}^{+} N_{2}^{-}}{N_{2}^{+} N_{1}^{-}} \) is a "super-ratio"

UCN residency time in bottle < 20s to limit depolarization...

from A. Young
2010 Beta-decay spectrum and ambient backgrounds

![Average β Spectrum](chart)

\[
S/B \ [200 < E \text{ keV} < 625] = 105
\]

from A. Young
Accidental cancellation makes $A_0$ small

$A_0 = -0.1173 \pm 0.0013$ (PDG 2010, expands error by 2.3)

Expanded error suggests inconsistent assessment of systematic errors in some of cold neutron beams experiments

**2011 UCNA Goal**: sub-0.4% measurement with complementary systematic errors to existing and planned cold neutron experiments

from A. Young
Bound Beta-Decay of the Neutron

Technische Universität München

\[ n \rightarrow H^0 + \bar{\nu} \]

\[ E_\nu = 783 \text{ keV} \]
\[ E_H = 352 \text{ keV} \]
\[ BR \approx 4 \times 10^{-6} \]

Measure hyperfine state population of H

- sensitive to small scalar and tensor contributions.
- yields constraint on neutrino left-handedness.

Typically, one measures the polarization of the final state products to determine correlations, where the products are the outgoing electron or proton.

However, one can measure precisely the relative spin alignments of the decay products into \( H \).

Radiative Neutron Decay

**Photon Energy Spectrum**

Radiative Neutron Decay - RDK I

- Previously unmeasured process in a fundamental semileptonic decay. Testing QED in a weak process.

Collaboration: NIST, Tulane, Maryland, Michigan, Sussex, Arizona State

RDK I operated at NIST NCNR cold neutron source. Measured e-Y coincidences followed by delayed proton.

\[ n \rightarrow p + e^- + \bar{\nu}_e + \gamma \]

Measured branching ratio:

\[ BR_{\text{RDK I}} = (3.13 \pm 0.34) \times 10^{-3} \]

\[ BR_{\text{QED}} = 2.81 \times 10^{-3} \]
Physics below 0.5%

- Physics with tagged photons
- Probe non-leading order terms: recoil terms, proton bremsstrahlung
- Photon polarization
- New classes of angular correlations, e.g. $A(J_n \cdot k)$, $D(J_n \cdot (k \times p_v))$, $(p_e \times p_v) \cdot k$. 

Gardner and He, arXiv:1101.1128v1
Why Time-Reversal Violation?

• CP violation exists:

  It was seen in neutral kaon decays in 1964 and neutral B mesons more recently.

• Preponderance of matter over antimatter:

  There isn’t sufficient CP violation in the Standard Model to account for baryogenesis.

• The Strong CP problem:

  Why is $\Theta_{QCD}$ so small?

• We know that the Standard Model is incomplete:

  Other theories generate phases significantly larger than the SM that would generate EDMs at levels within experimental reach.
Searching for Sources of Time-Reversal Violation

- Atomic and electron EDMs
- K and B mesons
- Neutron EDM
- Nuclear EDMs (Rn, Ra, Hg, Xe)
- Angular Correlations
Probing T-violation: an EDM

\[ H = - (\vec{\mu} \cdot \vec{B} + \vec{d} \cdot \vec{E}) \]

\[ \omega_1 = \frac{2\vec{\mu} \cdot \vec{B} + 2\vec{d} \cdot \vec{E}}{\hbar} \]

\[ \omega_2 = \frac{2\vec{\mu} \cdot \vec{B} - 2\vec{d} \cdot \vec{E}}{\hbar} \]

\[ \omega_1 - \omega_2 = \frac{4dE}{\hbar} \]
Probing T-violation: a correlation

\[
\frac{dW}{dE_e d\Omega_e d\Omega_v} = G(E_e) \left( 1 + a \frac{p_e \cdot p_v}{E_e E_v} + b \frac{m_e}{E_e} + p \cdot \left( A \frac{p_e}{E_e} + B \frac{p_v}{E_v} + D \frac{p_e \times p_v}{E_e E_v} \right) \right)
\]

T-odd, P-even

Not quite T reversal; Initial and final states are not reversed:
final state interactions:

\[ |D_{f.s.}| \sim 2 \times 10^{-5} \]

Time reversal violation in nuclear $\beta$-decay

- In the Standard Model the size of measured CP and T violating effects imply extremely tiny (non-observable) T violating effects in nuclear beta decay.

- Yet the observed matter - antimatter asymmetry indicates the existence of CP violation (and corresponding T-violation) perhaps arising from non-SM interactions.
  - Left-Right Symmetric
  - Exotic Fermion
  - Leptoquark

- T violating contributions to beta decay can arise from
  - Parity violating, Time reversal violating N-N interactions
  - Parity conserving, Time reversal violating N-N interactions
  - Time reversal violating charged current quark-lepton interactions

Searches for T violation in nuclear beta decay have the potential to be sensitive to interactions beyond the SM.
β-decay tests of T invariance

• Combine T-odd combinations of three kinematic variables
  \[ D\sigma_n \cdot (p_e \times p_v) \quad R\sigma_n \cdot (\sigma_e \times p_e) \]

• Require competing amplitudes with a relative phase
• Must account for final state effects

\(^{8}\text{Li}\)
  \[ R = (0.9 \pm 2.2) \times 10^{-3} \]

\(^{19}\text{Ne}\)
  \[ D = (1 \pm 6) \times 10^{-4} \]
  F. Calaprice, in Hyperfine Interactions (Springer, Netherlands, 1985), Vol. 22

neutron
  \[ R = (8 \pm 15\text{(stat.)} \pm 5\text{(syst.)}) \times 10^{-3} \]
  \[ D = (-2.8 \pm 7.1) \times 10^{-4} \]
  \[ D = (-6 \pm 12\text{(stat.)} \pm 5\text{(syst.)}) \times 10^{-4} \]
The emiT Experiment: A Search for Time-reversal Invariance Violation in Polarized Neutron Beta Decay

emiT measurement technique

- Symmetrical, segmented detector to minimize or cancel instrumental asymmetries that could yield false coincidences
- Detector geometry to maximize sensitivity to $D\sigma_n \cdot \{ p_e \times p_p \}$ (minimize sensitivity to other terms in decay distribution)
- emiT gained a factor of three increase in “effective” beam flux over previous “right angle” geometry beam experiments

**Challenges**
- **proton endpoint 750 eV** (requires acceleration)
- **Neutron lifetime** (requires intense source)
- Uniform magnetic guide fields
- Well defined and understood beam
emiT “blind” analysis

Efficiency independent ratio,

\[ w^{p_i e_j} = \frac{N_+^{p_i e_j} - N_-^{p_i e_j}}{N_+^{p_i e_j} + N_-^{p_i e_j}} + B\tilde{z} \cdot \tilde{K}_D^{p_i e_j} \]

hidden blind offset

\( w \) is sensitive to \( D \), but also to \( A, B \)

Define a parameter,

\[ \nu^{p_i} = \frac{1}{2}(w^{p_i R} - w^{p_i L}) \]

For a real detector,

\[ w^{p_i e_j} \approx P \cdot \left( A\tilde{K}_A^{p_i e_j} + B\tilde{K}_B^{p_i e_j} + D\tilde{K}_D^{p_i e_j} \right) \]
emiT Summary

Have completed the most sensitive measurement of the D coefficient in nuclear beta decay. (arXiv:1104.2778)

\[ D = (-0.96 \pm 1.89\text{(stat)} \pm 1.01\text{(sys)}) \times 10^{-4} \]
Future D measurement, emiT III?

- The new NGC beam line could provide over a factor of 10 increase in neutron flux.
- Current emiT apparatus might be capable of reaching $2-3 \times 10^{-5}$ with modest upgrades and improvements.
- At this level one should see the effect of final state effects.
- No definite plan at this time.
Observations

- Precision measurements in beta decay play an important role in searching for new physics and provide complementary information to high energy experiments.

- Many new experimental efforts are in progress to resolve differences. New UCN experiments should illuminate existing disagreement; results should be imminent (1-2 years).

- New high-flux facilities coming online world-wide for fundamental neutron physics: PSI, FRM-II, SNS, LANL, JSNS, NIST upgrade...

1) There are a large number of angular correlations, but $A$ (neutron spin - electron momentum) is the most frequently measured to determine lambda. Why is that?

[The reason can be shown with straightforward calculations.]

2) The angular correlation $a$ (electron momentum - antineutrino momentum) has nearly the sensitivity as $A$, but it has been measured with less precision. Speculate on the (experimental) reason why that is.

3) In the beam lifetime experiment, nowhere was the beam energy (i.e., velocity) discussed. It is a factor in the number of protons that are produced, so one might think that it must be known quite well. In fact, it is irrelevant. Speculate on the reason why.
