Recent Developments and Applications of Integral Transforms in Few- and Many-Body Physics

Outline

- Introduction
- Compton scattering (A=2)
- Δ degrees of freedom in $^3$He(e,e') (A=3)
- Role of $0^+$ resonance in $^4$He(e,e') (A=4)
- Density excitation response in bulk atomic $^4$He at T=0
Consider an observable $R(E)$ and an integral transform $\Phi(\sigma)$:

$$\Phi(\sigma) = \int dE \ K(\sigma,E) \ R(E)$$

with some kernel $K(\sigma,E)$

Often it is easier to calculate $\Phi(\sigma)$ than $R(E)$. Then the observable $R(E)$ can be obtained via inversion of the integral transform.

In order to make the inversion sufficiently stable the kernel $K(\sigma,E)$ should resemble a kind of energy filter (Lorentzians, Gaussians, ...); best choice would be a $\delta$-function.
In the following we will consider LITs (Lorentz integral transforms) with

\[ K(\sigma, E) = \left[ (E - \sigma_R)^2 + \sigma_I^2 \right]^{-1} \]

and Sumudu transforms with

\[ K_p(\sigma, E) = N \left( e^{-\mu E/\sigma} - e^{-\nu E/\sigma} \right)^p \]
Photon Scattering with the LIT method

(more details in G. Bampa, WL, H. Arenhövel, PRC 84, 034005)
Photon scattering

The photon scattering amplitude is given by two terms:

The contact or two photon amplitude (TPA) \( B_{\lambda',\lambda}(k',k) \) and the resonance amplitude (RA) \( R_{\lambda',\lambda}(k',k) \)
total scattering amplitude:

\[ T_{X'X}^{fi}(\vec{k}', \vec{k}) = B_{X'X}^{fi}(\vec{k}', \vec{k}) + R_{X'X}^{fi}(\vec{k}', \vec{k}), \]

TPA has the form:

\[ B_{X'X}^{fi}(\vec{k}', \vec{k}) = -\langle f | \int d^3x d^3y e^{i\vec{k}' \cdot \vec{x}} e^{-i\vec{k} \cdot \vec{y}} e^{i\tau_k} \cdot \vec{B} (\vec{x}, \vec{y}) \cdot e_X^* | i \rangle, \]

RA is given by

\[ R_{X'X}^{fi}(\vec{k}', \vec{k}) = \langle f | \left[ e^{\tau_k} \cdot \vec{J}(-\vec{k}', 2\vec{P}_f + \vec{k}') G(k + i\epsilon) e_X \cdot \vec{J}(\vec{k}, 2\vec{P}_i + \vec{k}) \\
+ e_X \cdot \vec{J}(\vec{k}, 2\vec{P}_f - \vec{k}) G(-k' + i\epsilon) e^{\tau_k} \cdot \vec{J}(-\vec{k}', 2\vec{P}_i - \vec{k}') \right] | i \rangle, \]

with intermediate propagator

\[ G(z) = (H - E_i - z)^{-1}. \]

Cartesian tensor operator \( B \) of rank 2 represents the second order term of the e.m. interaction
Intrinsic current $j$ plus a term taking into account the convection current of the separated cm-motion ($M$: nucleon mass, $A$: mass number of nucleus)

The intrinsic charge and current operators consist of one- and two- body parts

\[ \rho(\vec{k}) = \rho_{[1]}(\vec{k}) + \rho_{[2]}(\vec{k}), \]
\[ \vec{j}(\vec{k}) = \vec{j}_{[1]}(\vec{k}) + \vec{j}_{[2]}(\vec{k}), \]

\[ \rho_{[1]}(\vec{k}) = \sum_{l} e_{l} e^{-i\vec{k} \cdot \vec{r}_{l}}, \]
\[ \vec{j}_{[1]}(\vec{k}) = \frac{1}{2M} \sum_{l} \left( e_{l} \{ \vec{p}_{l}, e^{-i\vec{k} \cdot \vec{r}_{l}} \} + \mu_{l} \vec{\sigma}_{l} \times \vec{k} e^{-i\vec{k} \cdot \vec{r}_{l}} \right). \]

e$_{l}$, m$_{l}$, p$_{l}$, and $\sigma_{l}$: charge, magnetic moment, internal momentum, and spin operator of $l$-th particle
Low-energy limits

Resulting in the low-energy limit for the total scattering amplitude:

\[ T^{ii}_{\lambda',\lambda}(0,0) = -\vec{e}_{\lambda'} \cdot \vec{e}_\lambda \frac{(Ze)^2}{AM} , \]

which is the classical Thomson limit.
Reaction strength is described by polarizabilities

\[ P_{if, J}^{L' L \lambda' \lambda}(k', k) = \sum_{\nu' \nu = 0, 1} \chi^{\nu' \lambda' \nu} p_{if, J}(M^{\nu' L'}, M^\nu L, k', k), \]

- \( M^0 \): electric multipole
- \( M^1 \): magnetic multipole

Incoming photon transfers angular momentum \( L \)
Scattered photon transfers angular momentum \( L' \)
Total momentum transfer \( J \) to the nucleus with \(|L-L'| \leq J \leq L+L'|\)
Expansion of total scattering amplitude in terms of polarizabilities

\[
T_{\lambda\lambda}^{i\i}(\vec{k}', \vec{k}) = (-1)^{1+\lambda'+I_f-M_i} \sum_{L',M',L,M,J} (-)^{L+L'}(2J+1) \begin{pmatrix} I_f & J & I_i \\ -M_f & m & M_i \end{pmatrix} \begin{pmatrix} L & L' & J \\ M & M' & -m \end{pmatrix} 
\times P_{ij,f,J}^{L'L\lambda\lambda}(k',k)D_{M,\lambda}(R)D_{M',-\lambda'}^{L'}(R'),
\]

where \((I_i, M_i)\) and \((J_f, M_f)\) refer to the angular momenta and their projections on the quantization axis of the initial and final states.

The polarizabilities can be separated in a TPA and a RA contribution

\[
P_{ij,f,J}(M' L', M' L, k', k) = P_{ij,f,J}^{TPA}(M' L', M' L, k', k) + P_{ij,f,J}^{res}(M' L', M' L, k', k),
\]

W. Leidemann – INT program Sep. 17 – Nov. 16
Polarizability contribution for resonance amplitude:

\[
P^{\text{res}}_{if,J}(M^{\nu L}, M^{\nu L}, k', k) = 2\pi (-)^{L+J} \frac{\hat{L}' \hat{L}}{J} \times (I_f E_f \| \left[ \left( M^{\nu' L'}(k') G(k + i\varepsilon) M^{\nu L}(k) \right)^J + \left[ M^{\nu L}(k) G(-k' + i\varepsilon) M^{\nu' L'}(k') \right]^J \right) \| I_i E_i).
\]  

(small cm current contribution neglected)

Polarizability contribution for two-photon amplitude:

\[
P^{\text{TPA}}_{if,J}(M^{\nu' L'}, M^{\nu L}, k', k) = 2\pi (-)^{L+J+1} \frac{\hat{L}' \hat{L}}{J} (I_f E_f \| \int d^3x d^3y \left[ \vec{A}'^L(M^{\nu'}; k, \vec{x}) \cdot \vec{B}(\vec{x}, \vec{y}) \cdot \vec{A}^L(M^{\nu}; k, \vec{y}) \right]^J \| I_i E_i).
\]

Evaluation of the TPA contribution is straight forward once the TPA operator \( B(x,y) \) is given.
For the RA contribution one finds by evaluating the reduced matrix element in standard fashion

\[
P_{ij}(M',L',M,L,k,k) = 2\pi(-)^{L'+I_L-I_i} \hat{L}\hat{L}'
\]

\[
\times \sum_{J,I_n} \left\{ \begin{array}{ccc} L & L' & J \\ I_f & I_i & I_n \end{array} \right\} \frac{\langle I_f E_f | M',L' \rangle (k') |I_n E_n \rangle \langle I_n E_n | M',L \rangle (k) |I_i E_i \rangle}{E_n - E_i - k - i\varepsilon}
\]

\[+( - )^{L+L'+J} \left\{ \begin{array}{ccc} L' & L & J \\ I_f & I_i & I_n \end{array} \right\} \frac{\langle I_f E_f | M',L \rangle (k) |I_n E_n \rangle \langle I_n E_n | M',L' \rangle (k') |I_i E_i \rangle}{E_n - E_i + k' - i\varepsilon}
\]

Calculation of the RA part is more involved!
One has to sum over all possible intermediate states $|I_n> \text{ and energies } E_n$

For $k=0$ only the scalar $E_1-E_1$ polarizability is nonvanishing:

\[
P_J(E_1, E_1)|_{k=0} = -\delta_J \hat{I} \sqrt{3} \frac{e^2 Z^2}{M_A},
\]

(I is ground-state spin)
The scattering cross section

\[ \frac{d\sigma}{d\Omega} = \frac{k'}{k} \frac{c(k, p_i, k')}{2(2I_i + 1)} \sum_{\lambda, \lambda', M_i, M_f} |T_{\lambda' \lambda, M_f, M_i}^{fi}(k', k)|^2 , \]

with

\[ c(k, p_i, k') = \frac{\omega + E_i - \omega'}{(\omega + E_i)|k - \frac{\vec{p}_i}{E_i}|} . \]

E1 transitions only:

\[ \frac{d\sigma(E1)}{d\Omega} = \frac{k'}{k} \frac{c(k, p_i, k')}{(2I_i + 1)} \sum_{J} |P_{iJ}(E1, E1)|^2 g_{J}^{E1}(\theta) , \]

with

\[ g_{0}^{E1}(\theta) = \frac{1}{6} (1 + \cos^2 \theta) , \]
\[ g_{1}^{E1}(\theta) = \frac{1}{4} (2 + \sin^2 \theta) , \]
\[ g_{2}^{E1}(\theta) = \frac{1}{12} (13 + \cos^2 \theta) . \]
Application of the LIT method

Introduction of a polarizability strength function

\[
F_{(\nu'_{L'},\nu L)}^{I_f I_i}(k', k, E) = \frac{(-)^{J+I_f+I_i}}{\mathcal{J}} \langle I_f E_f || M^{\nu',L'}(k') \times \delta(H - E) M^{\nu,L}(k) \rangle^J || I_i E_i \rangle.
\]

In general the strength funcion is off-energy shell: \( E \neq E_i + k \).

One finds:

\[
F_{(\nu'_{L'},\nu L)}^{I_f I_i}(k', k, E) = \sum_{I_n} \rho(I_n, E) \left\{ \begin{array}{ccc}
L & L' & J \\
I_f & I_i & I_n
\end{array}\right\} \langle I_f E_f || M^{\nu',L'}(k') || I_n, E \rangle \langle I_n, E || M^{\nu,L}(k) || I_i E_i \rangle,
\]

\( \rho(I,E) \) is density of states for energy \( E \) and angular momentum \( J \)

Polarizability becomes

\[
P_{I_f,J}^{\text{res}}(M^{\nu',L'}, M^{\nu,L}, k', k) = 2\pi(-)^{L+I_f+I_i} \hat{L} \hat{L'}
\]

\[
\times \int_{E_0}^{\infty} dE \left[ \frac{F_{(\nu'_{L'},\nu L)}^{I_f I_i}(k', k, E)}{E - E_i - k - i\varepsilon} + (-)^{L+L'+J} \frac{F_{(\nu_{L'},\nu L)}^{I_f I_i}(k, k', E)}{E - E_i + k' - i\varepsilon} \right].
\]
Consider a fixed intermediate total angular momentum state $|I_n M_n >$

$F^{I_f I_i; I_n}_{\nu' L', \nu L}(k', k, E) = \rho(I_n, E) \langle I_f E_f \| M^{\nu', L'}(k') \| I_n, E \rangle \langle I_n, E \| M^{\nu, L}(k) \| I_i E_i \rangle.$

leads to following polarization strength

$F^{I_f I_i}_{(\nu', L', \nu L), J}(k', k, E) = \sum_{I_n} \left\{ \begin{array}{ccc} L & L' & J \end{array} \right\} F^{I_f I_i; I_n}_{\nu' L', \nu L}(k', k, E).$
The partial strength function can be calculated with the LIT method:

\[ L_{\nu', L', \nu L}^{I_f; I_i; I_n}(k', k, \sigma) = \int_{E_0}^{\infty} dE \frac{F_{\nu', L', \nu L}^{I_f; I_i; I_n}(k', k, E)}{(E - \sigma)(E - \sigma^*)}. \]

One finds:

\[ L_{\nu', L', \nu L}^{I_f; I_i; I_n}(k', k, \sigma) = \left( - \right)^{I_n - I_i + L - L' + \nu'} \rho(I_n, \sigma) \sum_{M_n} \left( \tilde{\psi}_{I_f; I_n M_n}^{\nu', L'}(k', \sigma) \right| \tilde{\psi}_{I_i; I_n M_n}^{\nu, L}(k, \sigma). \]

where the LIT state is obtained from:

\[ (H - \sigma^*) \left| \tilde{\psi}_{I_i; I_n M_n}^{\nu, L}(k, \sigma) \right> = \left| (M^{\nu, L}(k) \times \psi_{I_i}^{I_n M_n}(k, \sigma). \right> \]
Deuteron Case for elastic scattering

Calculation is made in the cm-system, where one has \( k = k' \)

only the dominant E1 transitions are considered taking the long wave length approximation (Siegert form)

\[
E_M^1 = i[H, D_M^1], \text{ where } D_M^1 = \frac{\sqrt{\alpha}}{3\sqrt{2}} rY_{1M}(\Omega)
\]

Thus only the polarizabilities \( P_J(E_1, E_1, k) \) with \( J = 0, 1, 2 \) contribute

E1-E1 polarization strength function:

\[
\tilde{F}_{E_1, E_1}^{11;j}(E) = \frac{F_{E_1, E_1}^{11;j}(E)}{(E - E_0)^2} \\
= (-)^{j-1} \sum_m \langle (D^1 \times \psi^1_d)_{jm} | \delta(H - E) | (D^1 \times \psi^1_d)_{jm} \rangle.
\]

W. Leidemann – INT program Sep. 17 – Nov. 16
LIT equation

\[ (H - \sigma^*) |\tilde{\psi}_{jm}(\sigma)\rangle = |(D^1 \times \psi^{1}_d)jm\rangle, \]

Expansion of LIT state

\[ \langle r, \Omega |\tilde{\psi}_{jm}(\sigma)\rangle = \frac{\sqrt{\alpha}}{r} \sum_{l=|j-1|}^{j+1} \Phi_{jl}(\sigma, r) \langle \Omega |l1 jm\rangle, \]

leads to following radial equations:

\[ \left[ -\frac{\hbar^2}{M} \left( \frac{d^2}{dr^2} - \frac{l(l+1)}{r^2} \right) - \sigma^* \right] \Phi_{jl}(\sigma, r) + \sum_{l'} V_{jl,l'} \Phi_{jl'}(\sigma, r) = \frac{\sqrt{2}}{6} r f_{jl}(r) \]

with

\[ f_{jl}(r) = \delta_{l1} w(r) + (-)^{j+1} 3 \sqrt{5} \hat{l} \begin{pmatrix} 2 & 1 & l \end{pmatrix} \begin{pmatrix} 2 & 1 & 1 \\ 0 & 0 & 0 \\ j & 1 & l \end{pmatrix} w(r), \]

resulting in three LITs

\[ L_j(\sigma) := (-)^{j-1} \frac{4\pi}{2j+1} \tilde{L}_{E1,E1}^{11,j}(\sigma) = \frac{4\pi}{2j+1} \sum_m \langle \tilde{\psi}_{jm}(\sigma) |\tilde{\psi}_{jm}(\sigma)\rangle = \alpha \sum_l \int_0^\infty |\Phi_{jl}(\sigma, r)|^2 dr, \]
Inversion of LIT $L_j(\sigma)$ gives function $F_j(E)$ and leads to polarization strength function

$$F_{E_1,E_1}^{11,j}(E) = \frac{(E-E_0)^2}{4\pi} \sum_j (-)^{j+1} \left\{ \frac{1}{1} \frac{1}{1} \frac{J}{j} \right\} F_j(E),$$

Then one has the following polarizabilities

$$\left( P_j^{\text{res}}(E_1,k) \right)_{Im} = -6\pi^2 F_{E_1,E_1}^{11,j}(k+E_0),$$

$$\left( P_j^{\text{res}}(E_1,k) \right)_{Re} = \frac{1}{\pi} \mathcal{P} \int dk' \left( P_j^{\text{res}}(E_1,k') \right)_{Im} \left( \frac{1}{k'-k} + \frac{(-)^J}{k'+k} \right).$$

Following results are obtained with Argonne v18 potential
Results for the LITs with $\sigma_I = 5$ MeV
Comparison of functions $F_j$ with standard calculation for full E1-operator.

![Graph showing comparison of functions $F_j$ with standard calculation for full E1-operator.](image)
Results for E1-E1 polarizabilities

- solid black lines: LIT results
- dotted blue line: full E1-operator
- dashed red line: inclusion of MEC (M. Weyrauch, H. Arenhövel, NPA 408, 425 (1983))
Cross section result

Note real parts of polarizabilities are normalized for $k = 0$ to obtain the correct low-energy result, i.e. classical Thomson limit for $J = 0$ and $\text{Re}(P_2(k=0)) = 0$ (implicit consideration of MEC contribution in both cases).
Δ degrees of freedom in $^3$He(e,e')

Example: $^2\text{H}(e,e')$

$^0\text{He}$ Resonance in the $^4\text{He}$ compound system

Resonance at $E_R = -8.2$ MeV, i.e. above the $^3\text{H}$-p threshold. Strong evidence in electron scattering off $^4\text{He}$

G.G. Simon et al., NPA 324, 277 (1979)

G. Köbschall et al., NPA 405, 648 (1983)
Standard LIT inversion method

Take the following ansatz for the response function \( R(\omega) \) (or \( F_{fi}(E,E') \))

\[
R(\omega') = \sum_{m=1}^{M_{\text{max}}} c_m \chi_m(\omega',\alpha_i)
\]

with \( \omega' = \omega - \omega_{\text{th}} \), given set of functions \( \chi_m \), and unknown coefficients \( c_m \).

Define:

\[
\tilde{\chi}_m(\sigma_R,\sigma_I,\alpha_i) = \int_0^\infty d\omega' \frac{\chi_m(\omega',\alpha_i)}{(\omega' - \sigma_R)^2 + \sigma_I^2}
\]

Take calculated LIT \( L(\sigma_R,\sigma_I) = \langle \tilde{\psi} | \tilde{\psi} \rangle \) for many \( \sigma_R \) and fixed \( \sigma_I \)

and expand in set \( \tilde{\chi}_m \):

\[
L(\sigma_R,\sigma_I) = \sum_{m=1}^{M_{\text{max}}} c_m \tilde{\chi}_m(\omega',\alpha_i)
\]

Determine \( c_m \) via best fit
Increase $M_{\text{max}}$ up to the point that stable result is obtained for $R(\omega)$. Even further increase of $M_{\text{max}}$ might lead to oscillations in $R(\omega)$

As basis set $\chi_m$ we normally use

$$\chi_m(\omega',\alpha_i) = (\omega')^{\alpha_1} \exp(-\alpha_2 \omega'/m)$$
\( \sigma_i = 0.001 \text{ MeV} \)
\[ \sigma_i = 0.001 \text{ MeV} \]

\[ \sigma_i = 1 \text{ MeV} \]
\( \sigma_i = 0.001 \text{ MeV} \)

\( \sigma_i = 1 \text{ MeV} \)

\( \sigma_i = 5 \text{ MeV} \)
The present precision of the calculation does not allow to resolve the shape of the resonance, therefore the width cannot be determined.
The present precision of the calculation does not allow to resolve the shape of the resonance, therefore the width cannot be determined.

However, the strength of the resonance can be determined!
The present precision of the calculation does not allow to resolve the shape of the resonance, therefore the width cannot be determined.

However, the strength of the resonance can be determined!

Of course not by taking the strength to the discretized state, but by rearranging the inversion in a suitable way:
The present precision of the calculation does not allow to resolve the shape of the resonance, therefore the width cannot be determined.

However, the strength of the resonance can be determined!

Of course not by taking the strength to the discretized state, but by rearranging the inversion in a suitable way:

Reduce strength to the state up to the point that the inversion does not show any resonant structure at the resonance energy $E_R$:

$$\text{LIT} (\sigma_R, \sigma_I) \rightarrow \text{LIT} (\sigma_R, \sigma_I) - f_R \left/ \left[ (E_R - \sigma_R)^2 + \sigma_I^2 \right] \equiv \text{LIT} (\sigma_R, \sigma_I, f_R)$$

with resonance strength $f_R$. 

W. Leidemann – INT program Sep. 17 – Nov. 16
Determination of resonance strength $f_R$
Determination of resonance strength $f_R$

Include in the inversion a basis function with resonant structure

$$\chi_1(E') = \frac{1}{\left[(E_R - E')^2 + \Gamma^2 / 4\right]}$$

and check inversion result.
Determination of resonance strength $f_R$

Include in the inversion a basis function with resonant structure

$$\chi_1(E') = \frac{1}{[(E_R - E')^2 + \Gamma^2 / 4]}$$

and check inversion result.

Vary LIT($\sigma_R, \sigma_I, f_R$) by changing $f_R$ up to the point that no resonant structure is present. Then $f_R$ corresponds to the resonance strength.
Inversion results with different $f_R$ values
AV18+UIX, $q=300$ MeV/c
($\Gamma = 0.1$ MeV)
Inversion results with different $f_R$ values
AV18+UIX, $q=300$ MeV/c ($\Gamma = 0.1$ MeV)
Results for the resonance strength and comparison to experimental data

\( e^{-\tau E} \)

Laplace kernel

In Condensed Matter Physics:

\( \Theta = \) Density Operator

\( S(E) = \) Dynamical Structure Function

In Nuclear Physics:

\( \Theta = \) Charge or current density operator

\( S(E) = R(E) \) “Response” Function

In QCD

\( \Theta = \) quark operators

\( S(E) = \) Hadronic Spectral Function
A good kernel for Monte Carlo methods:
(A.Roggero, F. Pederiva, G.Orlandini 2012)

combination of Sumudu kernels:

\[ K_P(\omega, \sigma) = N \left( e^{-\mu \omega/\sigma} - e^{-\nu \omega/\sigma} \right)^P \]

\[ \nu/\mu = b/a \quad \nu - \mu = (\ln[b] - \ln[a])/(b-a) \]

\[ K_P(\omega, \sigma) \xrightarrow{P \to \infty} \delta(\omega - \sigma) \]

b > a > 0 integer
Density excitation response in bulk atomic $^4$He at $T = 0$

\[ S(Q, \omega) \text{ [arb. units]} \]

\begin{align*}
\text{Th: } Q &= 0.4 \text{ A}^{-1} \quad T=0 \\
\text{Exp: } Q &= 0.44 \text{ A}^{-1} \quad T = 1.35 \text{ K}
\end{align*}
