

# Hard probes in isobar collisions & nuclear structures

Intersection of nuclear structure and high-energy nuclear collisions

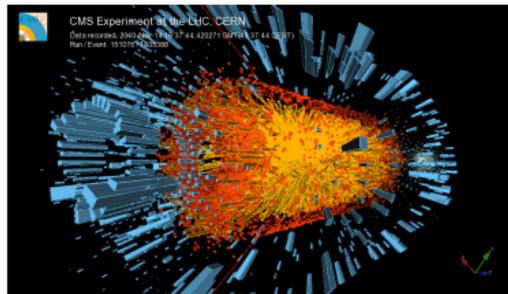

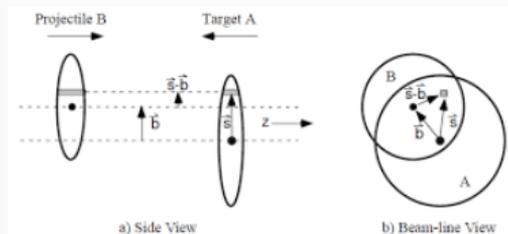

INT 23-1a program, Week 2, Feb 1, 2023

---

**Weiyao Ke**, Los Alamos National Laboratory

- Hard probes in heavy-ion collisions
- Different scaling of hard and soft particle production.
- Sensitivity of isospin dependent probes  $W^-/W^+$  to neutron skin.
- Improving the Monte-Carlo Glauber modeling in isobar collisions.

# Particle productions in heavy-ion collisions

- High energy collisions:  $\gamma \gg 1$ . Spatial information in  $z$  highly compressed.
- Initial particle productions are localized in transverse plane. Nuclear geometry only enters in the form of thickness functions

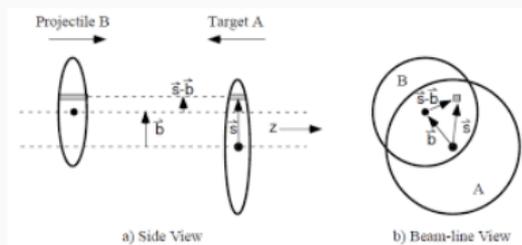

$$T_A(x_{\perp}) = \int \rho_A(x_{\perp}, z) dz$$

$$T_B(x_{\perp}) = \int \rho_B(x_{\perp}, z) dz$$

# From geometry to cross sections: the Glauber model

$AB$  cross sections from  $NN$  cross sections and thickness functions

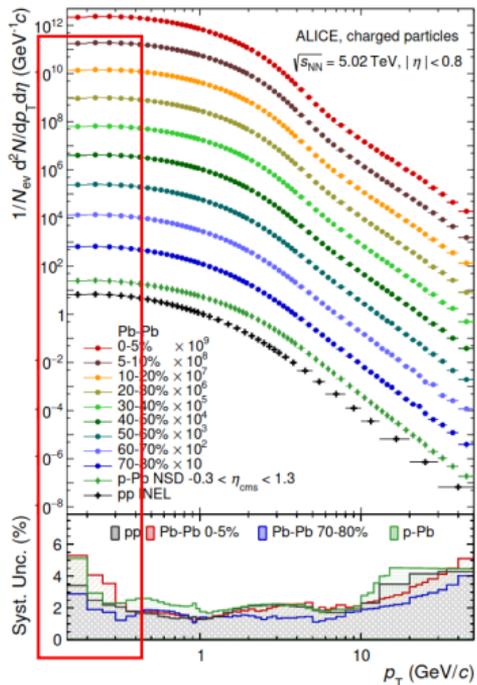

$$\begin{aligned}\sigma_{AB} &= \int d^2b \left[ 1 - \left[ 1 - \sigma_{NN} \frac{\int_{x_{\perp}} d^2T_A(x_{\perp}) T_B(b - x_{\perp})}{AB} \right]^{AB} \right] \\ &\approx \int d^2b \left[ 1 - \exp \left\{ - \int d^2x_{\perp} \sigma_{NN \rightarrow X} T_A(x_{\perp}) T_B(b - x_{\perp}) \right\} \right]\end{aligned}$$

- If  $X$  is a frequent process,  $\sigma_{AB}$  follows the geometric area.
- If  $X$  is a rare process, such as high- $p_T$  jets, weak bosons

$$\sigma_{AB \rightarrow X} = \int d^2b \int d^2x_{\perp} \sigma_{NN \rightarrow X} T_A(x_{\perp}) T_B(b - x_{\perp})$$

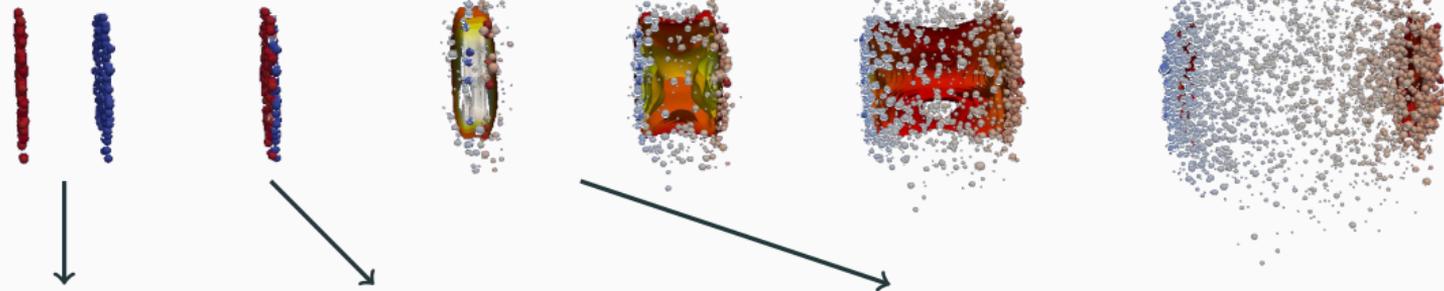

# Scaling of bulk (soft) hadron production

- $p_T \lesssim 1 \text{ GeV}$ . High multiplicity, approximately goes like number of participants  $N_{part}$ ,  

$$\int_x T_A(x)(1 - e^{-\sigma_{NN} T_B(b^-)}) + T_B(b-x)(1 - e^{-\sigma_{NN} T_A(x)})$$
- Charged particle multiplicity strongly correlates with impact parameter, events classified by centrality.
- Bulk particles at middle rapidity are produced from small- $x$  content of the nucleus, isospin insensitive.

# Final-state dynamics contributing to particle production

Nuclear structure  
parameters

$$T_A(x_{\perp}; R, a, \beta \dots)$$

Initial energy deposition.

A major source of uncertainty.

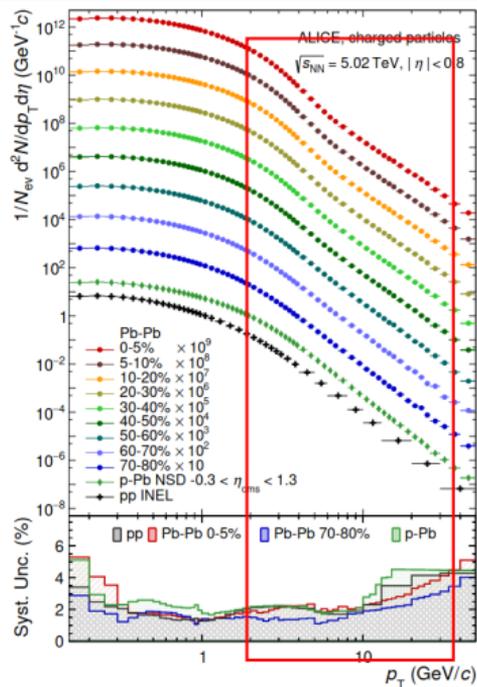

- $T_A(x), T_B(x) \rightarrow e(x_{\perp}, \eta_s)$ .
- Granularity, initial flow,  $\dots$

Dynamical response

- Geometry  $\rightarrow$  momentum-space information, entropy production.
- Relies on transport parameters.

Current accuracy for **a single system**  $\sim 5 - 10\%$   
from global fits Jetscaoe PRC103(2021)054904

# Production of hard probes in HIC

ALICE Pb-Pb,  $pp$  @ 5.02 TeV

- High- $p_T$  processes, well-known production mechanism with high accuracy in  $pp$ .

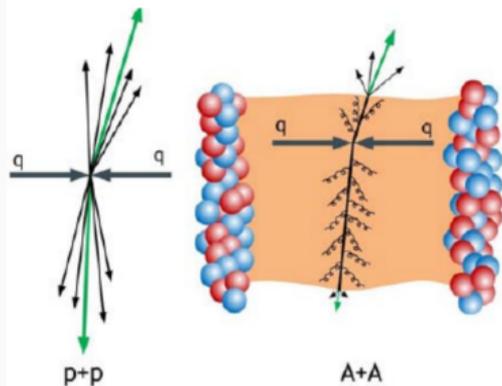

$$\sigma_{NN \rightarrow h} = f_{i/N} f_{j/N} \otimes \hat{\sigma}_{ij \rightarrow k} \otimes D_{h/k}(z)$$

- A traditional observable: nuclear modification factor

$$R_{AA} = \frac{1}{\langle T_{AA} \rangle} \frac{dN_{AA \rightarrow h}}{d\sigma_{pp \rightarrow h}}$$

- $T_{AA} = N_{\text{coll}} / \sigma_{pp, \text{inel}}$ . If  $AA$  are independent superposition of free  $NN$  collisions, then  $R_{AA} = 1$ .

# Production of hard probes in HIC

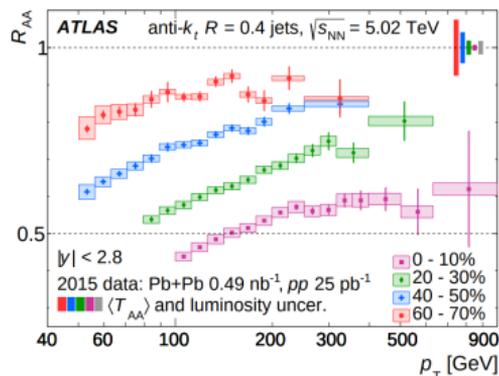

- High- $p_T$  processes, well-known production mechanism with high accuracy in  $pp$ .

$$\sigma_{NN \rightarrow h} = f_{i/N} f_{j/N} \otimes \hat{\sigma}_{ij \rightarrow k} \otimes D_{h/k}(z)$$

- A traditional observable: nuclear modification factor

$$R_{AA} = \frac{1}{\langle T_{AA} \rangle} \frac{dN_{AA \rightarrow h}}{d\sigma_{pp \rightarrow h}}$$

- $T_{AA} = N_{\text{coll}} / \sigma_{pp, \text{inel}}$ . If  $AA$  are independent superposition of free  $NN$  collisions, then  $R_{AA} = 1$ .
- Colorful probes (high- $p_T$  hadrons, jets) are suppressed from parton energy loss / modified fragmentations in QGP modifications  $D_{h/k}(z; T(x), u^\mu(x))$  in QGP.

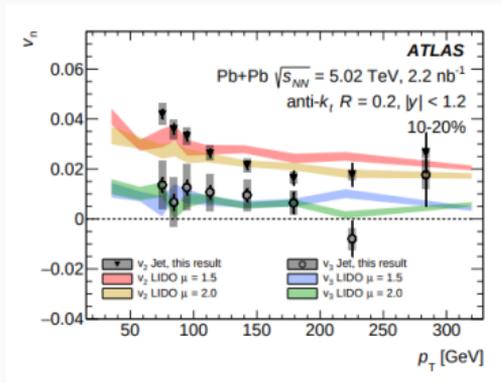

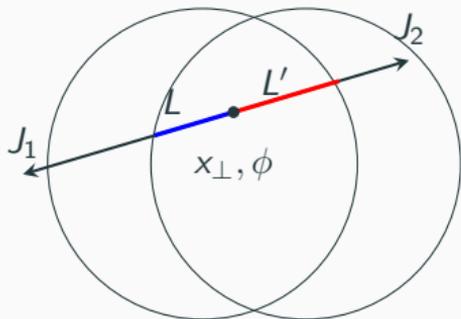

ATLAS jet  $R_{AA}$ , PLB790 (2019)108

# Probing fireball geometry with jets

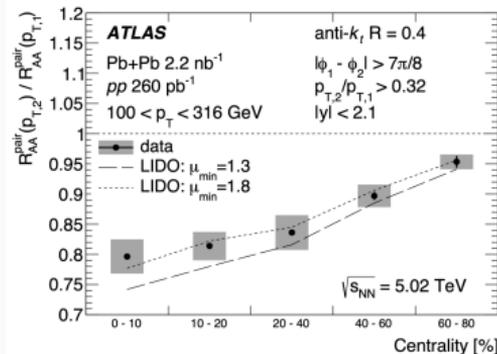

- Jet probes path-length integrated QGP fireball information.
- In a weakly-coupled picture, parton energy loss in QGP (jet energy loss more involved)

$$\Delta E = \underbrace{\frac{C_R}{4} \int_0^L \alpha_s(ET) \ln \frac{ET}{m_D^2} m_D^2 d\tau}_{\text{Collisional}} + \underbrace{\alpha_s C_R \int_0^L \hat{q}_g(\tau) \tau d\tau \ln \frac{2E}{m_D^2 \tau}}_{\text{GLV type radiative energy loss}} + \dots$$

- Average over jet production locations ( $\propto T_A(x_\perp) T_B(x_\perp)$ ) and orientations  $\phi$ .
- Correlating high- $p_T$  hadron/jet with soft-particle event plane  $\Rightarrow$  finite high- $p_T$   $v_n$ .

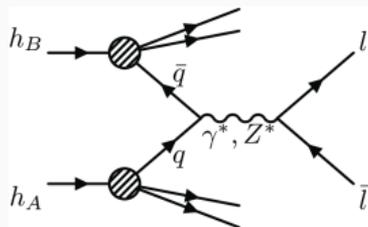

ATLAS: jet  $v_2, v_3$ .

Subleading/leading jet  $R_{AA} \rightarrow$  consider an isobar ratio?

# Colorless probes: $W^\pm, Z$ bosons

Lepton	$2c_V$	$2c_A$	Quark	$2c_V$	$2c_A$
$\nu_e, \nu_\mu, \nu_\tau$	1	1	$u, c, t$	$1 - \frac{8}{3} \sin^2 \theta_W$	1
$e, \mu, \tau$	$-1 + 4 \sin^2 \theta_W$	-1	$d, s, b$	$-1 + \frac{4}{3} \sin^2 \theta_W$	-1

$W, Z$  do not interact with QGP, all modifications come from initial states.

$$\sigma_{AB \rightarrow W, Z}(x_\perp) = \phi_{i/A}(x_1, Q^2; x_\perp) \phi_{j/B}(x_2, Q^2; b - x_\perp) \otimes \hat{\sigma}_{ij \rightarrow W, Z} \otimes \Gamma_{W \rightarrow l\nu_l}, \Gamma_{Z \rightarrow l+l^-}$$

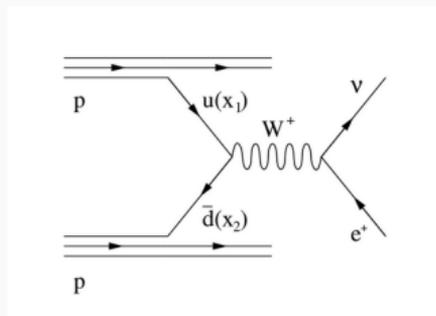

- Local parton luminosity  $\phi_{i/A} \phi_{j/B}$ .

$$\phi_{i/A}(x_1, Q^2; x_\perp) \rightarrow T_{p/A}(x_\perp) f_{i/p}^A(x_1, Q^2; T_A(x_\perp)) + T_{n/A}(x_\perp) f_{i/n}^A(x_1, Q^2; T_A(x_\perp))$$

$f_{i/p}^A$  and  $f_{i/n}^A$  related by isospin symmetry.

- Nuclear PDFs differ from free proton PDF. Modifications are often assumed to only depend on local thickness. Though most parametrizations only have  $f_{i/p}^A(x_1, Q^2; A)$ .
- How much do nuclear PDF uncertainty cancels in isobar ratios?

# Colorless probes: $W^\pm, Z$ bosons

$$\begin{bmatrix} |V_{ud}| & |V_{us}| & |V_{ub}| \\ |V_{cd}| & |V_{cs}| & |V_{cb}| \\ |V_{td}| & |V_{ts}| & |V_{tb}| \end{bmatrix} = \begin{bmatrix} 0.97370 \pm 0.00014 & 0.2245 \pm 0.0008 & 0.00382 \pm 0.00024 \\ 0.221 \pm 0.004 & 0.987 \pm 0.011 & 0.0410 \pm 0.0014 \\ 0.0080 \pm 0.0003 & 0.0388 \pm 0.0011 & 1.013 \pm 0.030 \end{bmatrix}$$

$W, Z$  do not interact with QGP, all modifications come from initial states.

$$\sigma_{AB \rightarrow W, Z}(x_\perp) = \phi_{i/A}(x_1, Q^2; x_\perp) \phi_{j/B}(x_2, Q^2; b - x_\perp) \otimes \hat{\sigma}_{ij \rightarrow W, Z} \otimes \Gamma_{W \rightarrow l\nu_l}, \Gamma_{Z \rightarrow l+l^-}$$

- Local parton luminosity  $\phi_{i/A} \phi_{j/B}$ .

$$\phi_{i/A}(x_1, Q^2; x_\perp) \rightarrow T_{p/A}(x_\perp) f_{i/p}^A(x_1, Q^2; T_A(x_\perp)) + T_{n/A}(x_\perp) f_{i/n}^A(x_1, Q^2; T_A(x_\perp))$$

$f_{i/p}^A$  and  $f_{i/n}^A$  related by isospin symmetry.

- Nuclear PDFs differ from free proton PDF. Modifications are often assumed to only depend on local thickness. Though most parametrizations only have  $f_{i/p}^A(x_1, Q^2; A)$ .
- How much do nuclear PDF uncertainty cancels in isobar ratios?

NLO hard cross-section.

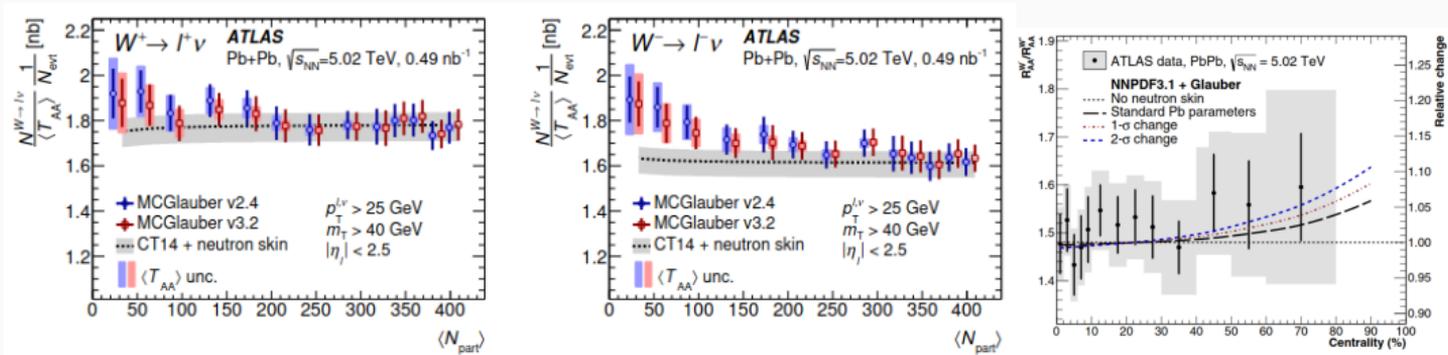

# Weak boson production in Pb Pb at 5.02 TeV

ATLAS: EPJC79(2019)935, PLB802(2020)135262

- Already at the level showing deviations of the default Glauber model. Also note the large  $\langle T_{AA} \rangle$  uncertainty.
- $W^\pm$  can be sensitive to neutron skin.

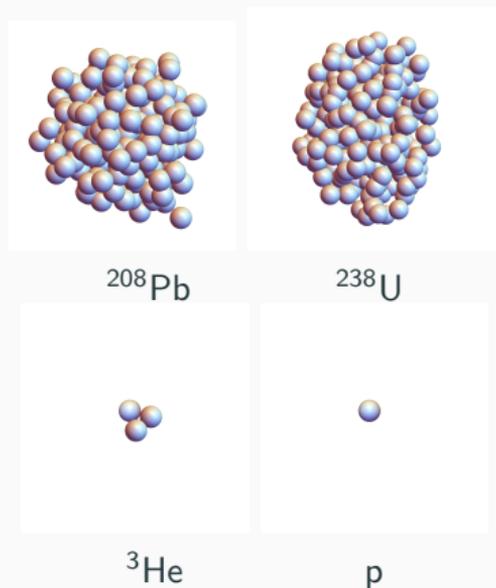

# Weak boson production in Pb Pb at 5.02 TeV

Neutron skin effect calculations: H. Paukkunen PLB745(2015)73-78 (left); F. Jonas, C. Loizides PRC104(2021)044905 (right).

- Already at the level showing deviations of the default Glauber model. Also note the large  $\langle T_{AA} \rangle$  uncertainty.
- $W^{\pm}$  can be sensitive to neutron skin.

# The TRENTo model<sup>1</sup>

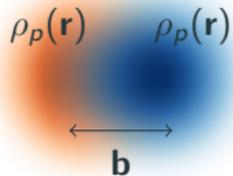

- Heavy nucleus:  $\frac{A}{\mathcal{N}} \frac{1}{1+\exp\left(\frac{r-R(\theta,\phi;\beta_n)}{a}\right)}$  deformation parameters from [Atom.Data Nucl.Data Tabl. 109-110 (2016) 1].
- $\min r_{ij} > d_{\min}$  to mimic short-range repulsion.
- Light nuclei: load samples of nuclear configurations from nuclear structure calculations, e.g.,  ${}^3\text{He}$  [PLB 680, 225–230 (2009)].

This study includes  $\beta_3$  deformation and two sets of WS parameters  $(R, a, \beta_2, \beta_3, \dots)$ ,  $\rho_p \neq \rho_n$  + evaluation of different types of binary collisions  $N_{pp}, N_{pn}, N_{nn}$ .

<sup>1</sup>TRENTo: JS Moreland, JE Bernhard, SA Bass, PRC 92, 011901 (2015), <http://qcd.phy.duke.edu/trento/index.html>

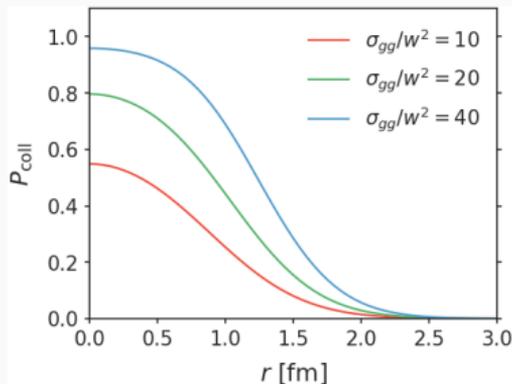

# Nucleon profile and $N$ - $N$ inelastic cross section

Nucleon model #1: Gaussian proton

$$\rho_p(\mathbf{r}, z) = \frac{e^{-\frac{r^2+z^2}{2w^2}}}{(2\pi w)^{3/2}} \xrightarrow{\int dz} \rho_p(\mathbf{r}) = \frac{e^{-\frac{r^2}{2w^2}}}{2\pi w^2}$$

Probability of inelastic collisions at fixed impact parameter.

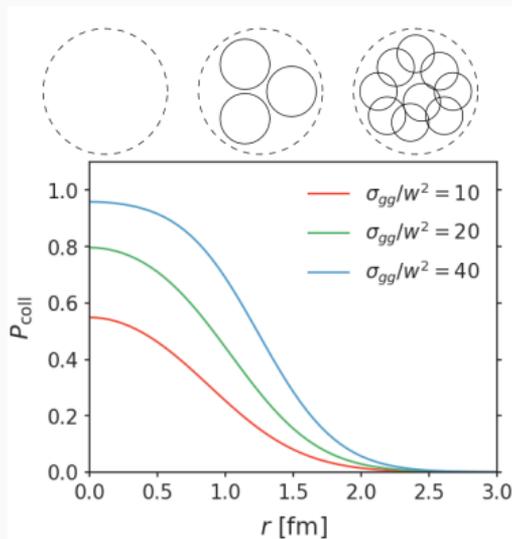

$$T_{pp}(b) = \int \rho_p(\mathbf{r} - \mathbf{b}/2) \rho_p(\mathbf{r} + \mathbf{b}/2) d^2\mathbf{r}$$

$$P_{\text{coll}}(b) = 1 - \exp\{-\sigma_{gg} T_{pp}(b)\}$$

$\sigma_{gg}$ : effective opacity parameter tuned to reproduce  $\sigma_{pp}^{\text{inel}}(\sqrt{s})$

$$\sigma_{pp}^{\text{inel}} \sqrt{s} = \int P_{\text{coll}}(\mathbf{b}; \sigma_{gg}(\sqrt{s})) d\mathbf{b}^2$$

# Nucleon profile and N-N inelastic cross section

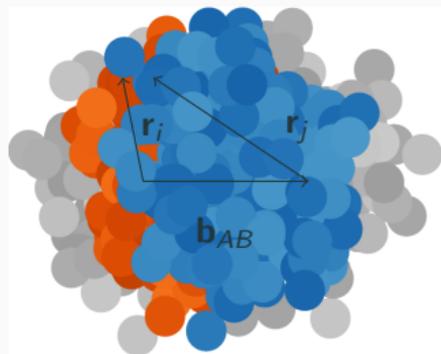

Nucleon model #2: with substructures [JS moreland, JE Bernhard, SA Bass, PRC 101, 024911]

$$\rho_p(r) = \frac{1}{N} \sum_{i=1}^N \frac{e^{-\frac{(r-r_i-R_{\text{cm}})^2}{2w_c^2}}}{2\pi w_c^2}, r_i \sim \frac{e^{-\frac{r_i^2}{2w'^2}}}{2\pi w'^2}$$

$R_{\text{cm}}$  fix the center of mass.

$\sigma_{gg}$  solved by Monte Carlo integration to reproduce  $\sigma_{pp}^{\text{inel}}(\sqrt{s})$ .

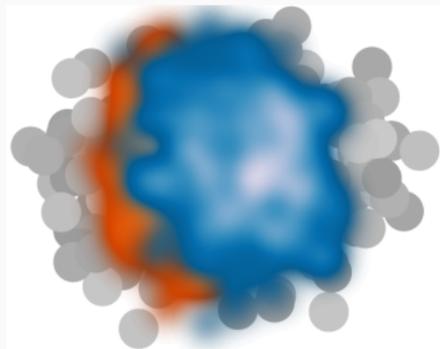

# Binary collisions and fluctuating participants density

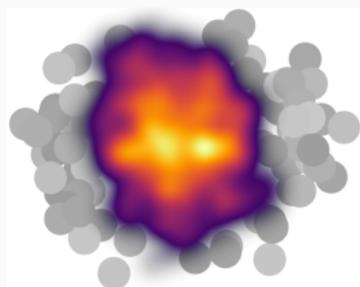

- Participant nucleons determined by sampling binary collision probability  $P_{\text{coll}}(b = |\mathbf{r}_j - \mathbf{b}_{AB} - \mathbf{r}_i|)$ .
- Fluctuating participant density:

$$T_{A \text{ or } B}(\mathbf{r}) = \sum_{i \in \text{Part. } A \text{ or } B} \gamma_i \rho_p(\mathbf{r} - \mathbf{r}_i)$$

- $P(\gamma_i) \propto \gamma^{k-1} e^{-k\gamma}$ . Emulate fluctuation in  $pp$  measurement, can change with kinematic cuts!

# Energy density production at mid-rapidity

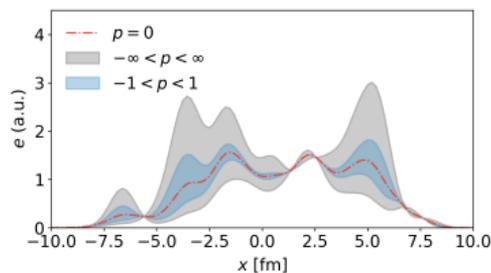

$$\frac{dE_T}{dx_{\perp}^2 d\eta_s}(x_{\perp}, \eta_s = 0) = \text{Norm} \times f(T_A(x_{\perp}), T_B(x_{\perp}))$$

TRENT0 assumes

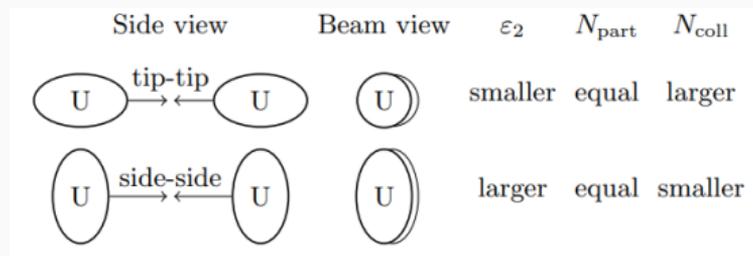

$$f(T_A, T_B) = \left( \frac{T_A^p + T_B^p}{2} \right)^{1/p}$$

known as “generalized mean” ( $p$ -mean) ansatz.

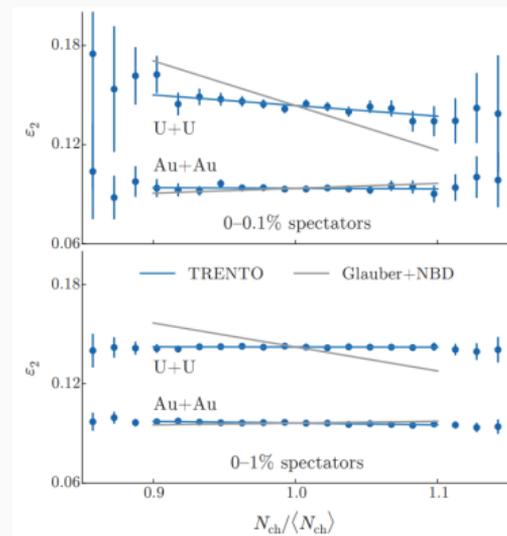

# A motivation of using $p$ -mean

$p$ -mean is “homogeneous”  $f(kT_A, kT_B) = kf(T_A, T_B)$ .  
Binary collisions ( $T_A T_B$ ) is not.

If  $N_{\text{coll}}$  involved, fine binning of  $N_{\text{ch}}$  should differentiate  $\epsilon_2 \triangleright$ .

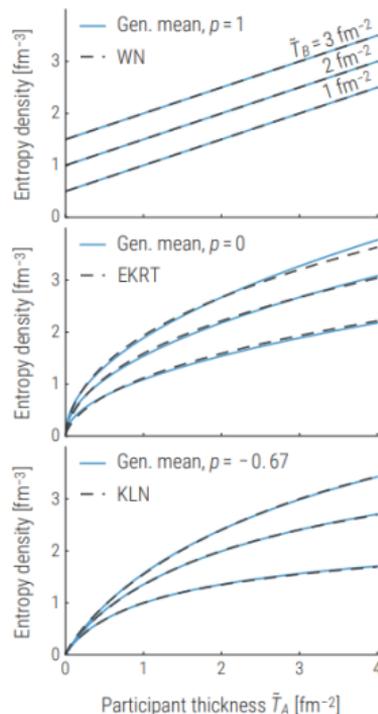

[JS Moreland, JE Bernhard, SA Bass, PRC 92, 011901 (2015)]

$p$ -mean is a class of energy deposition consistent with this observation.

Two-component Glauber  $N_{\text{ch}} \propto (1 - x)N_{\text{part}} + xN_{\text{coll}}$  is not consistent.

# Connections to scaling of other models

- Wounded nucleon model

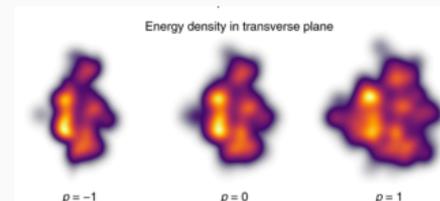

$$\frac{dS}{dy d^2r_{\perp}} \propto \tilde{T}_A + \tilde{T}_B$$

- EKRT model PRC 93, 024907 (2016) after brief free streaming phase

$$\frac{dE_T}{dy d^2r_{\perp}} \sim \frac{K_{\text{sat}}}{\pi} p_{\text{sat}}^3(K_{\text{sat}}, \beta; T_A, T_B)$$

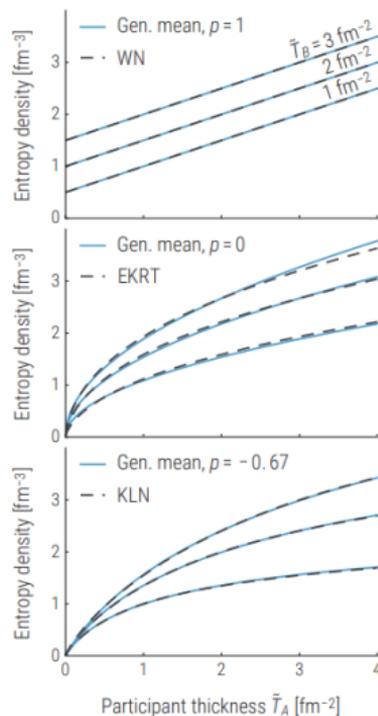

- KLN model PRC 75, 034905 (2007)

$$\frac{dN_g}{dy d^2r_{\perp}} \sim Q_{s,\text{min}}^2 \left[ 2 + \log \left( \frac{Q_{s,\text{max}}^2}{Q_{s,\text{min}}^2} \right) \right]$$

Still, only a subclass of existing models.

# Connections to scaling of other models

- Wounded nucleon model

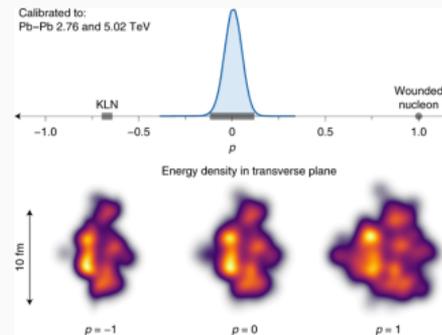

$$\frac{dS}{dy d^2r_{\perp}} \propto \tilde{T}_A + \tilde{T}_B$$

- EKRT model [PRC 93, 024907 \(2016\)](#)  
after brief free streaming phase

$$\frac{dE_T}{dy d^2r_{\perp}} \sim \frac{K_{\text{sat}}}{\pi} p_{\text{sat}}^3(K_{\text{sat}}, \beta; T_A, T_B)$$

- KLN model [PRC 75, 034905 \(2007\)](#)

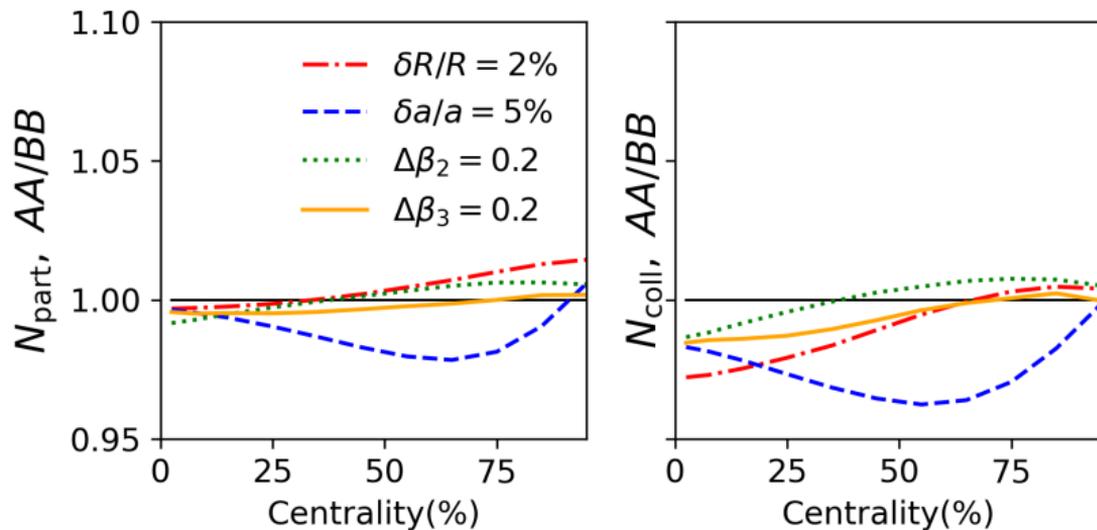

$$\frac{dN_g}{dy d^2r_{\perp}} \sim Q_{s,\text{min}}^2 \left[ 2 + \log \left( \frac{Q_{s,\text{max}}^2}{Q_{s,\text{min}}^2} \right) \right]$$

Bayesian analysis PbPb at LHC  
[Duke PRC 94 024907].

[JS Moreland]

## Variation of Woods-Saxon parameters

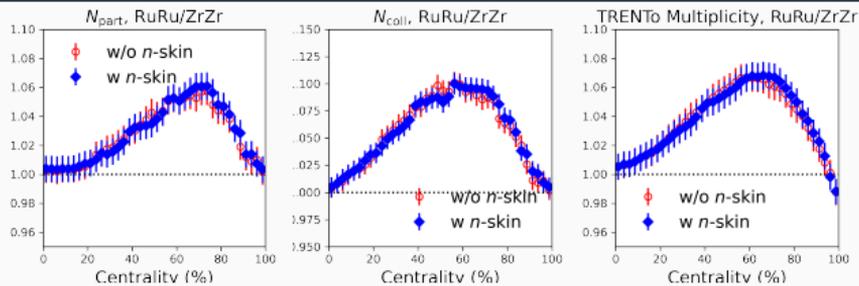

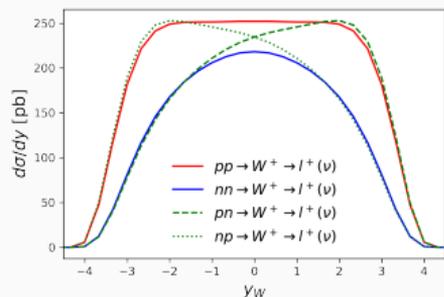

- Number of binary collision very sensitive to diffuseness and radius.
- In general,  $N_{\text{coll}}$  displays larger variation than  $N_{\text{part}}$ .

# Differentiating $N_{pp}$ , $N_{pn}$ , $N_{nn}$ when $\rho_n \neq \rho_p$

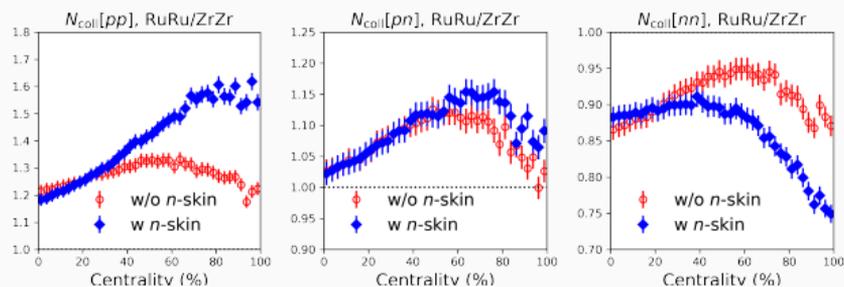

Table 2: The WS parameterizations (radius parameter  $R$  and diffuseness parameter  $a$ ) of proton and neutron (and nucleon) density distributions for  $^{96}\text{Ru}$  and  $^{96}\text{Zr}$ , matching to the corresponding  $\langle r \rangle$  and  $\langle r^2 \rangle$  from the DFT-calculated spherical densities with SLy4 skyrme parameter set [123]. The WS parameterization of nucleon density assuming a quadrupole deformity parameter  $\beta_2 = 0.16$  and matching to the spherical DFT density is also listed. All quoted numbers are in fm.

	$^{96}\text{Ru}$		$^{96}\text{Zr}$		
	$R$	$a$	$R$	$a$	
$\beta_2 = 0$	p	5.060	0.493	4.915	0.521
	n	5.075	0.505	5.015	0.574
	p+n	5.067	0.500	4.965	0.556
$\beta_2 = 0.16$	p	5.053	0.480	4.912	0.508
	n	5.073	0.490	5.007	0.564
	p+n	5.065	0.485	4.961	0.544

H.J. Xu et al., PLB819(2021)136453

- Parameter sets w/ and w/o neutron skin gives identical  $N_{\text{part}}$ /multiplicity,  $N_{\text{coll}}$  v.s. centrality.
- Deviations from unity coming from  $R, a$ .

- Neutron-skin-sensitive quantity:  $N_{pp}$ ,  $N_{pn}$ ,  $N_{nn}$

# Centrality dependent weak boson production

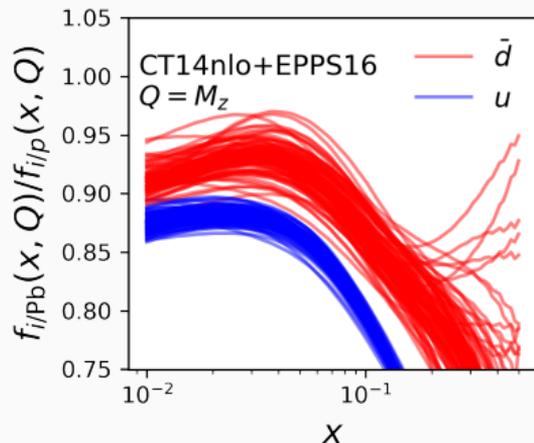

For an event-averaged collision with  $\langle N_{pp} \rangle$ ,  $\langle N_{pn} \rangle$ ,  $\langle N_{np} \rangle$ ,  $\langle N_{nn} \rangle$ ,

$$\frac{d\sigma_{W^+}}{dMdy} = \langle N_{pp} \rangle \frac{d\sigma_{pp \rightarrow W^+}}{dy} + \langle N_{pn} \rangle \frac{d\sigma_{pn \rightarrow W^+}}{dMdy} + \langle N_{np} \rangle \frac{d\sigma_{np \rightarrow W^+}}{dMdy} + \langle N_{nn} \rangle \frac{d\sigma_{nn \rightarrow W^+}}{dMdy}$$

Including decay width for  $W \rightarrow e\nu_e, \mu\nu_\mu$  and  $Z \rightarrow e^+e^-, \mu^+\mu^-$ , then integrated over the resonance peak (narrow resonance approximation formula from PRD69(2004)094008).

$$\begin{aligned} \frac{d\sigma_{W^\pm \rightarrow l\nu_l}}{dy} &\approx [3.327 \text{ GeV}] \times \left. \frac{d\sigma_{W^\pm}}{dMdy} \right|_{M=m_W}, \\ \frac{d\sigma_{Z \rightarrow l^+l^-}}{dy} &\approx [3.919 \text{ GeV}] \times \left. \frac{d\sigma_Z}{dMdy} \right|_{M=m_Z}. \end{aligned}$$

# Nuclear PDF uncertainty

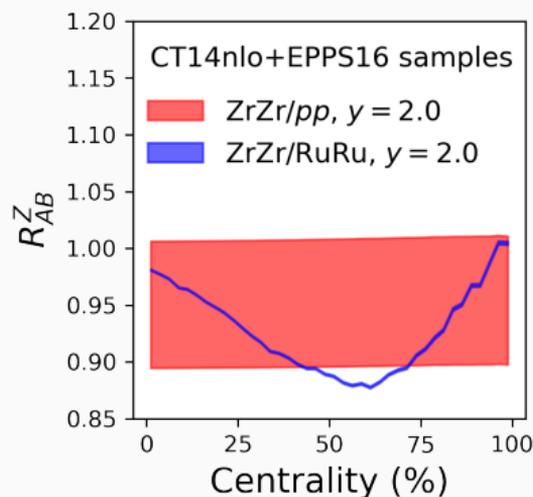

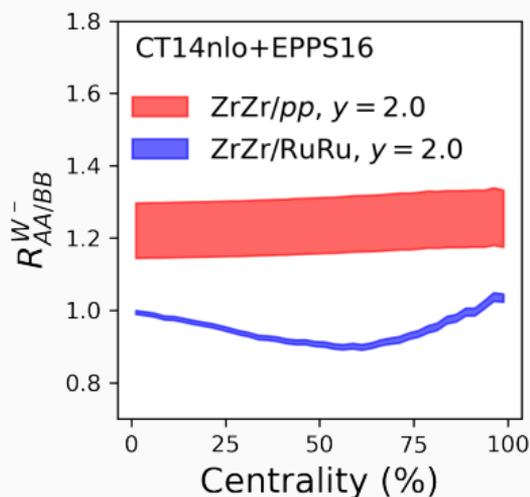

Proton PDF: CT14nlo, S. Dulat et al., PRD93(2016)033006.

Nuclear PDF: EPPS16, K. Eskola et al., EPJC77(2017)163.

- A major uncertainty for hard process calculation in  $AA$  is the nuclear PDF uncertainty.
- In  $R_{AA} = \frac{\sigma_{AA \rightarrow Z}}{\langle N_{\text{coll}} \rangle \sigma_{pp \rightarrow Z}}$ , about 10% uncertainty. Furthermore, nuclear PDF modulations can be impact-parameter dependent, not included in EPPS16.
- Nuclear PDF are often assumed to be isospin independent  $f_{u/p} = f_{d/n}$ . Modifications only depends on  $A$  or the thickness (deformation?).

# Reducing nPDF uncertainty by taking isobar ratio $(W, Z)_{AA/BB}$

- If there is only A dependence, nPDF uncertainty almost “cancels” in isobar ratio:  $\frac{\sigma_{RuRu \rightarrow Z}}{\sigma_{ZrZr \rightarrow Z}}$ .
- What about impact-parameter/thickness dependent nPDF?

Two crude ways to introduce neutron skin, just to estimate the sensitivity:

1. Change the Woods-Saxon diffuseness parameter  $a_p = a - \delta a/2$ ,  $a_n = a + \delta a/2$ .

Assume  $\delta a = \frac{N-Z}{A} \times 0.8$  fm, corresponding to  $\sqrt{\langle r_n^2 \rangle} - \sqrt{\langle r_p^2 \rangle} \approx 0.231$  fm for  $^{208}\text{Pb}$ .

2. Or, change the Woods-Saxon  $R$  parameter  $R_p = R - \delta R/2$ ,  $R_n = R + \delta R/2$ .

$\delta R = \frac{N-Z}{A} \times \delta R_0$  tuned to maintain the same neutron skin for each nucleus.

$$\begin{aligned}
 N_i &= \# \text{ of months} \times \int_{\text{month}} L_{\text{AA}} dt \\
 &\times \text{Centrality Percentage} \\
 &\times \sum_{a,b \in p,n} N_{ab} \frac{d\sigma_{ab \rightarrow W}}{dM dy} \\
 &\otimes \Gamma_{W \rightarrow l\nu_l} \times 2 \times \Delta y_l
 \end{aligned}$$

- Assumes 100% efficiency of  $W \rightarrow e\nu_e, \mu\nu_\mu, Z \rightarrow e^+e^-, \mu^+\mu^-$ .
- Measurements covers  $|y| < 2.5$ .
- Statistical uncertainty:  $N_i \pm \sqrt{N_i}$ .

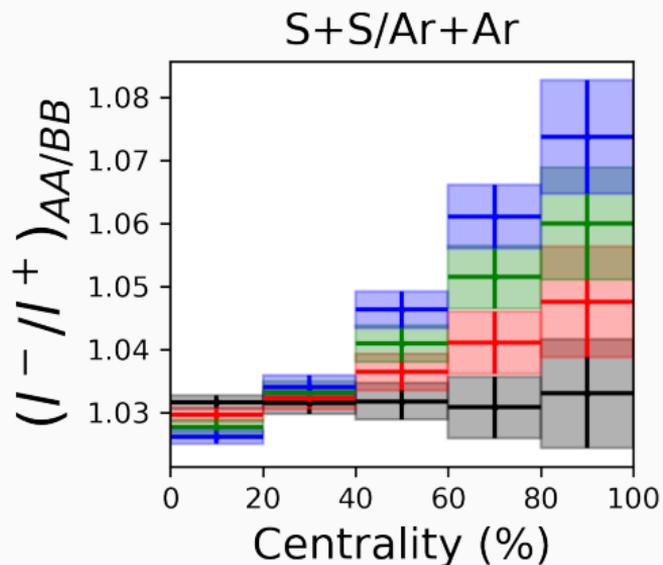

- Lines:  $N_{coll}$  vs Centrality.
- Black:  $\delta a = 0$ . Green:  $a_{n,p} = a \pm \delta a$ . Red:  $a_{n,p} = a \pm \frac{1}{2}\delta a$ . Blue:  $a_{n,p} = a \pm \frac{3}{2}\delta a$ .
- Z boson isobar ratio closely follows the  $N_{part}$  scaling remarkably well.

# Double ratio $[W^-/W^+]_{AA/BB}$

- One can study the double ratio  $(W^-/W^+)_{AA/BB}$  or  $(W/Z)_{AA/BB}$  to probe the evolution of  $p/n$  over centrality (impact parameter).
- Taking  $W^-/W^+$  ratio further cancels biases in peripheral collisions from triggering on a hard process.

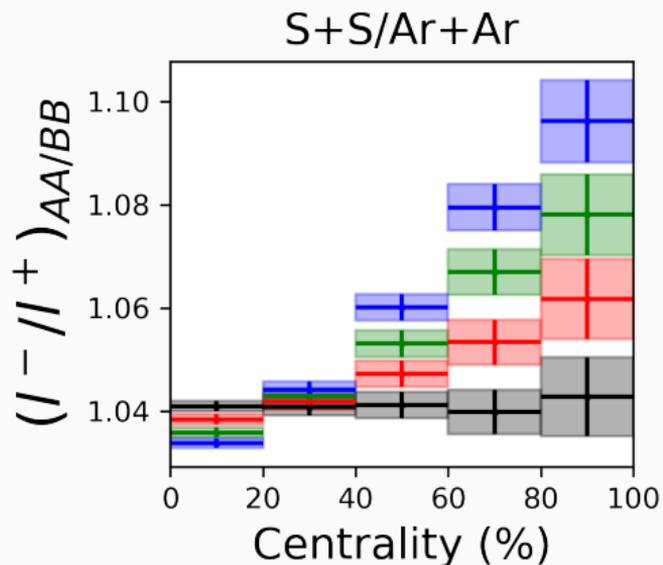

# Double ratio: ${}^{36}_{16}\text{S}$ vs ${}^{36}_{18}\text{Ar}$

- 3 TeV + 3 TeV,  $\sqrt{s} = 6$  TeV,  $y_{\text{com}} = 0$ ,  $|y_l| < 2.5$ .
- Notable increase of double ratio from central to peripheral collisions.
- Green:  $a_{n,p} = a \pm \delta a$ .
- Red:  $a_{n,p} = a \pm \frac{1}{2}\delta a$ .
- Blue:  $a_{n,p} = a \pm \frac{3}{2}\delta a$ .

$R = 3.56$  fm,  $a = 0.5$  fm, vary  $\delta a$ .

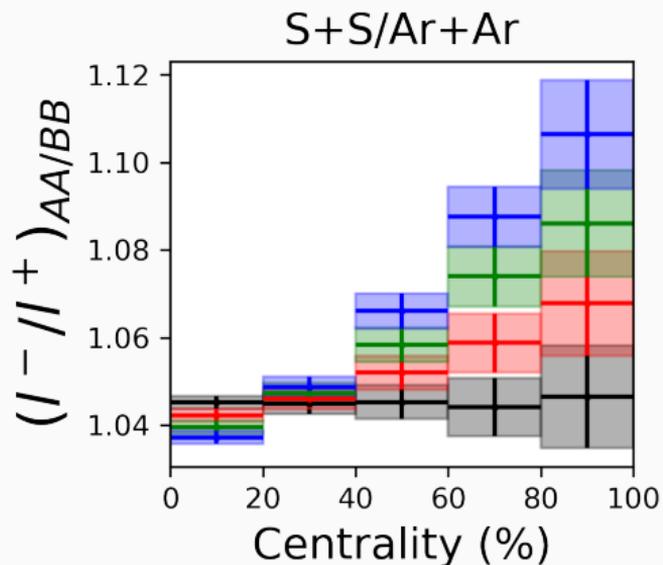

# Double ratio: ${}^{36}_{16}\text{S}$ vs ${}^{36}_{18}\text{Ar}$

- 3 TeV + 3 TeV,  $\sqrt{s} = 6$  TeV, **full rapidity coverage.**
- Notable increase of double ratio from central to peripheral collisions.
- **Green:**  $a_{n,p} = a \pm \delta a$ .
- **Red:**  $a_{n,p} = a \pm \frac{1}{2}\delta a$ .
- **Blue:**  $a_{n,p} = a \pm \frac{3}{2}\delta a$ .

$R = 3.56$  fm,  $a = 0.5$  fm, vary  $\delta a$ .

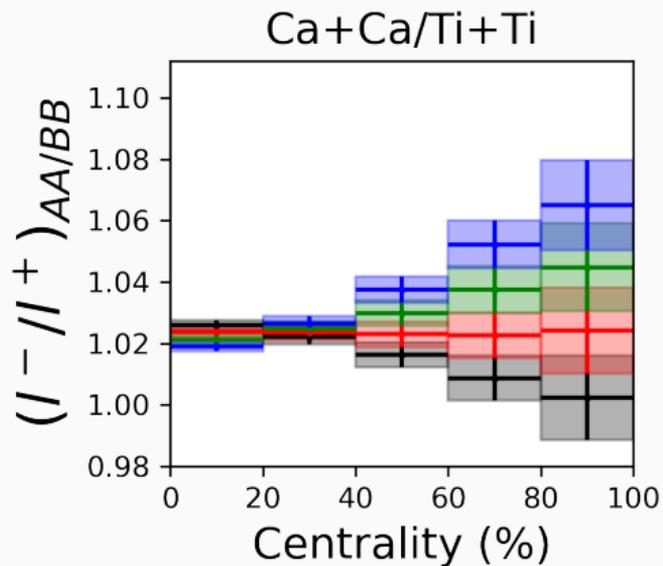

# Double ratio: ${}^{36}_{16}\text{S}$ vs ${}^{36}_{18}\text{Ar}$

- **3 TeV + 1 TeV**,  $\sqrt{s} = 3.46$  TeV,  
 $y_{\text{com}} = 0.55$ ,  $|y_l| < 2.5$ .
- Notable increase of double ratio from central to peripheral collisions.
- **Green**:  $a_{n,p} = a \pm \delta a$ .
- **Red**:  $a_{n,p} = a \pm \frac{1}{2} \delta a$ .
- **Blue**:  $a_{n,p} = a \pm \frac{3}{2} \delta a$ .

$R = 3.56$  fm,  $a = 0.5$  fm, vary  $\delta a$ .

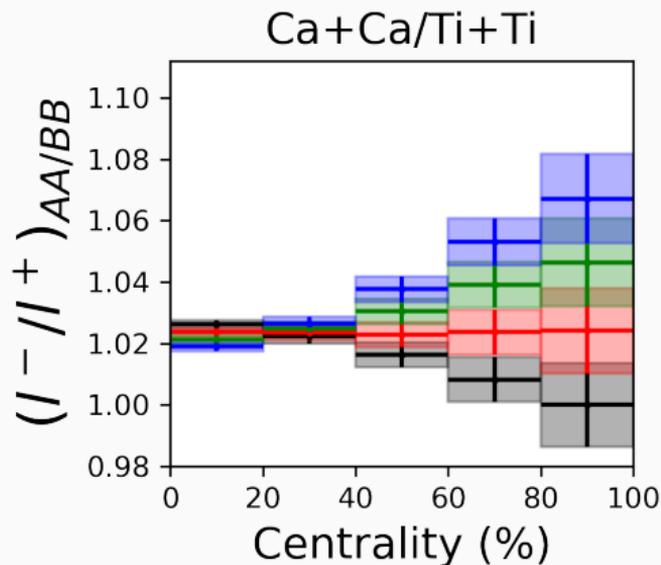

# Double ratio: ${}^{48}_{20}\text{Ca}$ vs ${}^{48}_{22}\text{Ti}$

- $\sqrt{s} = 6$  TeV,  $y_{\text{com}} = 0$ ,  $|y_l| < 2.5$ .
- Varying  $\delta a$  for Ca.

$R = 3.92$  fm,  $a = 0.5$  fm, changing  $a_p, a_n$

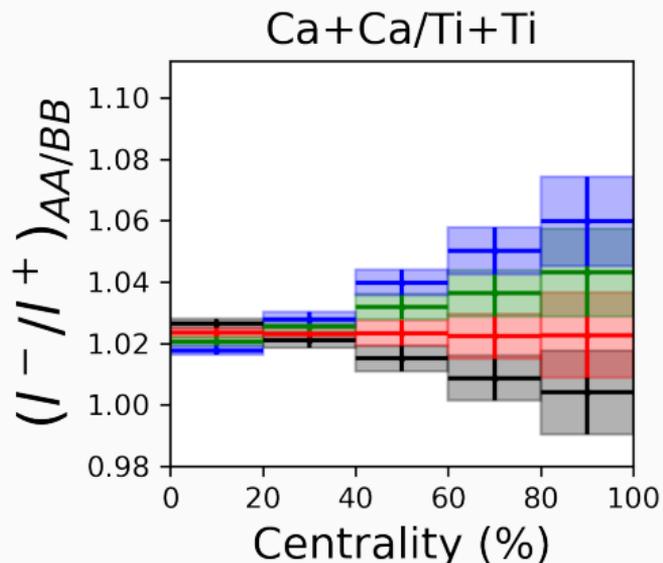

# Double ratio: ${}^{48}_{20}\text{Ca}$ vs ${}^{48}_{22}\text{Ti}$

- $\sqrt{s} = 6$  TeV,  $y_{\text{com}} = 0$ ,  $|y_l| < 2.5$ .
- Varying  $\delta a$  for Ca.
- The double ratio is no longer sensitive to isospin insensitive parameters.  
 $a_{\text{Ca}} : 0.5 \rightarrow 0.45$  fm, increase  $d$  to maintain the same neutron skin thickness.

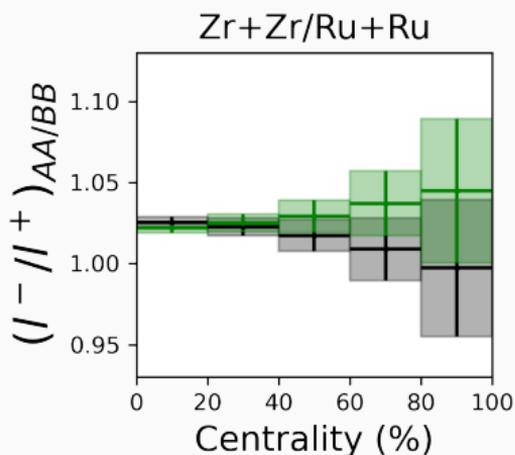

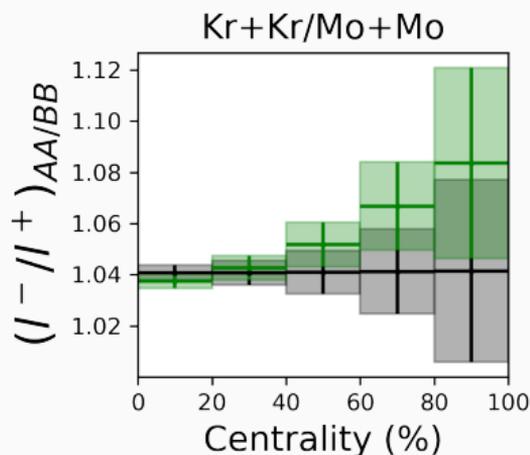

$R = 3.92$  fm,  $a = 0.45$  fm, changing  $a_p, a_n$

## Double ratio: ${}^{48}_{20}\text{Ca}$ vs ${}^{48}_{22}\text{Ti}$

$R = 3.92$  fm,  $a = 0.5$  fm, changing  $R_p, R_n$

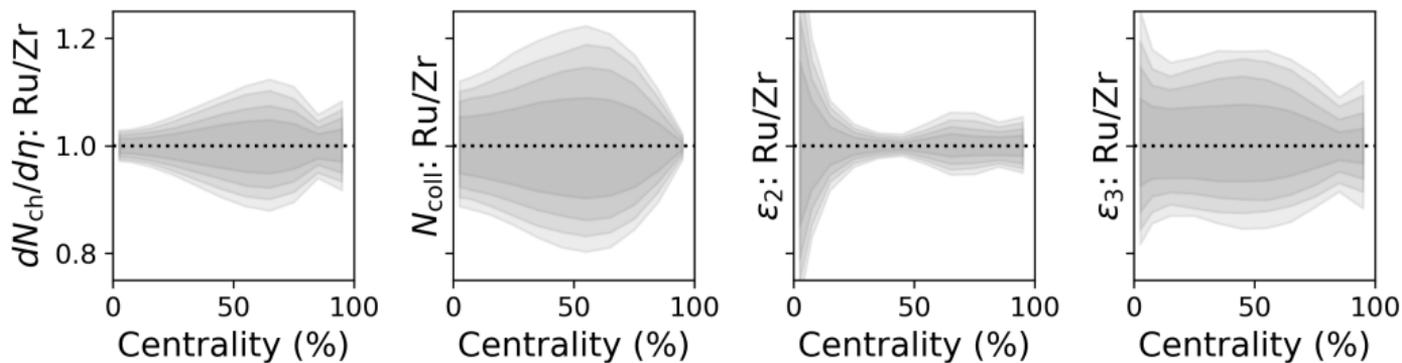

- $\sqrt{s} = 6$  TeV,  $y_{\text{com}} = 0$ ,  $|y_l| < 2.5$ .
- Varying  $\delta a$  for Ca.
- The double ratio is no longer sensitive to isospin insensitive parameters.  
 $a_{\text{Ca}} : 0.5 \rightarrow 0.45$  fm, increase  $d$  to maintain the same neutron skin thickness.
- Change  $R$  instead of  $a$ .

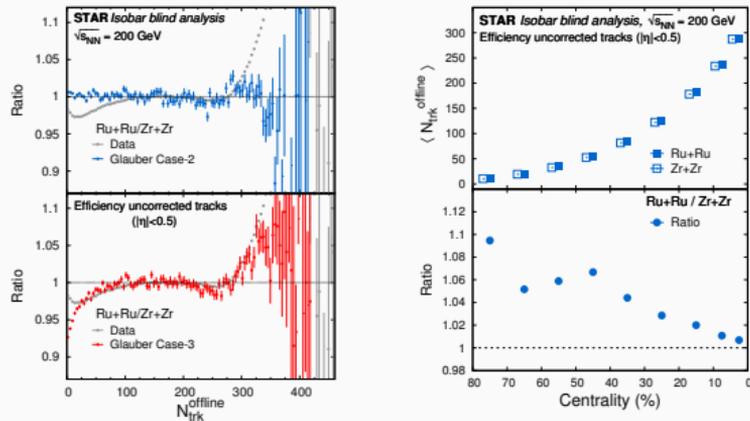

- $\sqrt{s} = 6$  TeV,  $y_{\text{com}} = 0$ ,  $|y| < 2.5$ .
- Currently still limited by luminosity.
- Explore other isospin sensitive probes, e.g., jet charge; in UPC events?
- Future Circular Collider?

## Z boson isobar ratio: hard collision input

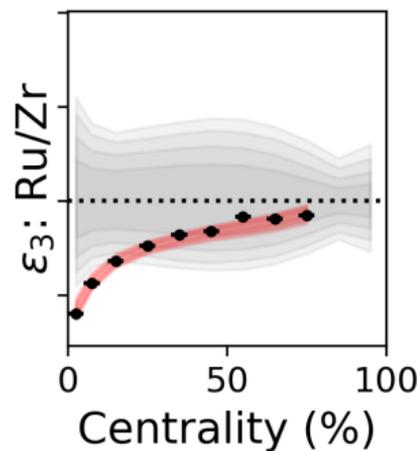

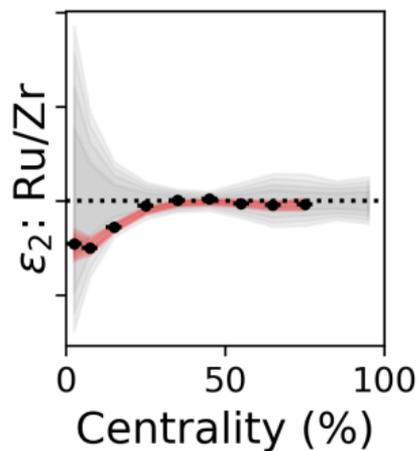

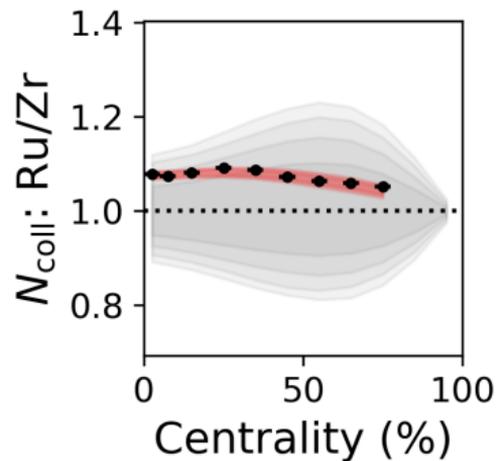

- $0 < \beta_{2,Ru}, \beta_{2,Zr} < 0.35$ .
- $0 < \beta_{3,Ru}, \beta_{3,Zr} < 0.35$ .
- $4.9 < R_{Ru}, R_{Zr} < 5.1$  fm.
- $0.4 < a_{Ru}, a_{Zr} < 0.6$  fm.
- $-0.1 < p < 0.1$ , from early studies.
- $0.4 < w < 1.0$  fm, nucleon width.
- $1/3 < k < 3$ , fluctuation.
- $0 < d < 1.5$  fm, repulsion.

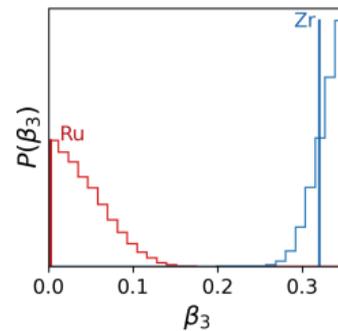

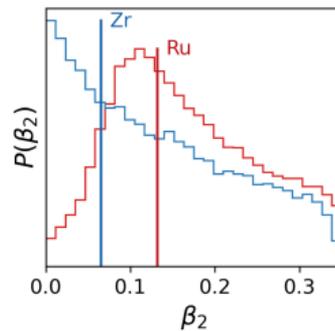

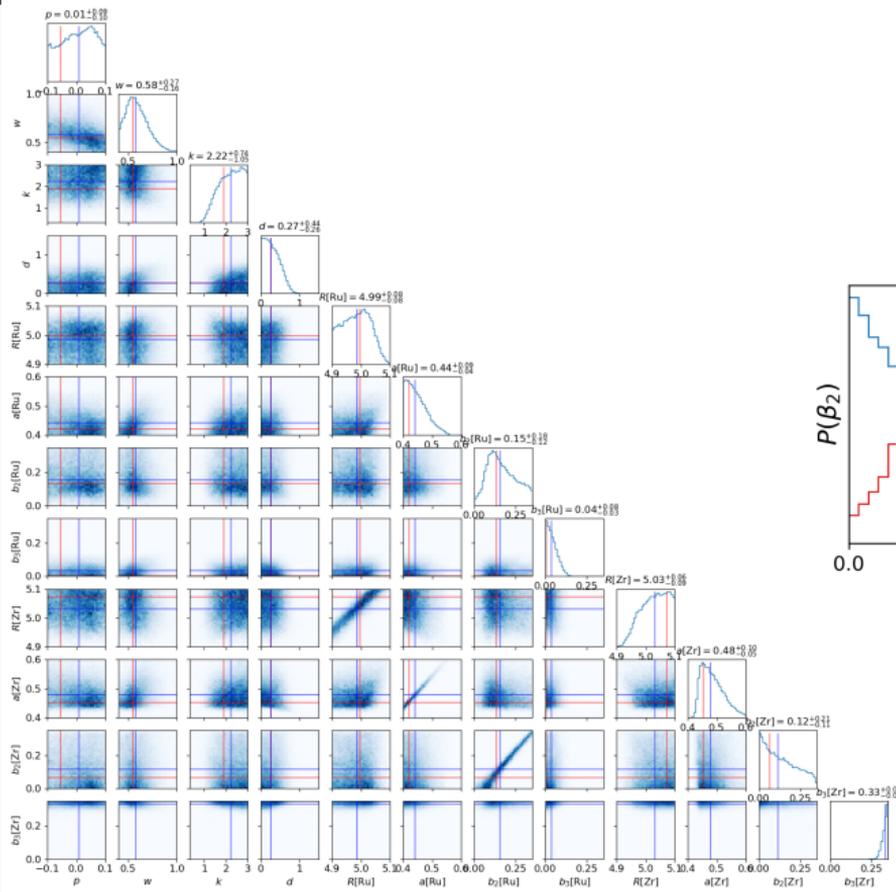

- Very high precision measurements: multiplicity, flow, etc.
- Still challenging for models of final-state interaction. Previous Global fits usually agree with multiplicity and flow data within 5-10% uncertainty.
- Independent input from hard scatterings can be useful.

## Binary collision + flow ratios

# Binary collision + flow ratios: woods-Saxon parameters

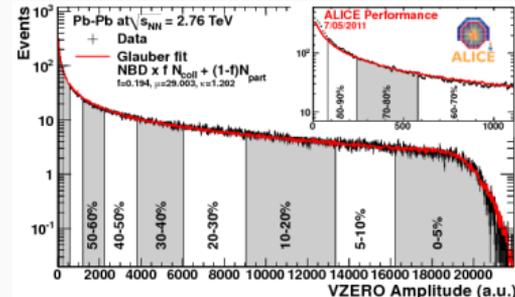

## Summary

- Hard probes  $N_{\text{coll}}$  have different scaling from soft hadron production  $\approx N_{\text{part}}$ , Z-boson isobar ratios can be used as independent inputs to constrain initial condition model.
- $W^\pm$  are very clean probes of isospin differences of isobar pairs.
- The centrality dependent isobar double ratio  $(W^-/W^+)_{AA/BB}$  probes neutron skin and cancels a large fraction of theory and modeling uncertainty.
- May be viable for light nuclei at HL-LHC (e.g., S vs Ar, Ca vs Ti), heavy nuclei are limited by statistics.
- Jets/hadrons: isobar ratio of self normalized new observables, study path-length distributions.

Questions?

# Nuclear/nucleon configurations & total cross-section

Centrality: percentage of minimum-bias hadronic cross section Pb-Pb@2.76 TeV  $770 \pm 10(\text{stat.})_{-50}^{+60}(\text{sys.})\text{fm}^2$   
**8% level.** [ALICE PRL 109 252302, PRC 88 044909].

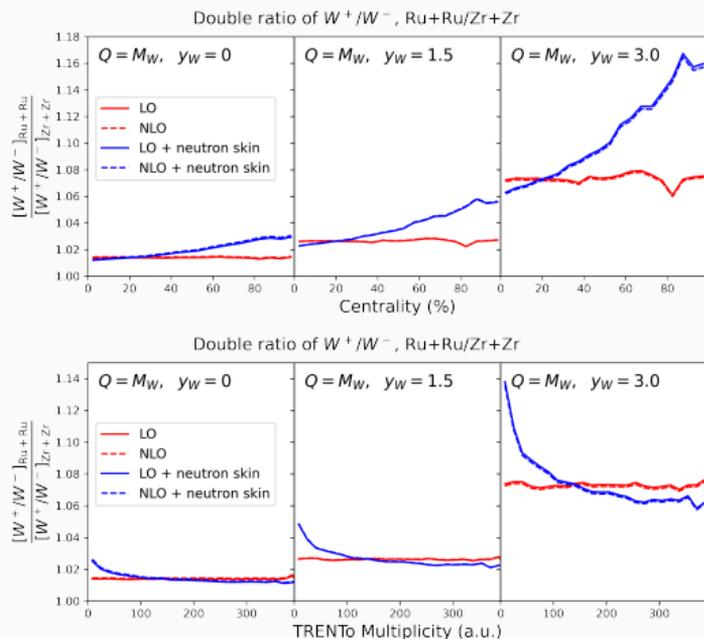

In Glauber-based models, including TRENTo

- Gaussian nucleon  $w$  and  $\beta$  can affect the total cross section:

$$\sigma_{\text{PbPb}}^{\text{TRENTo}}[w = 0.5 \text{ fm}] = \mathbf{782 \pm 4 \text{ fm}^2} \text{ vs } \sigma_{\text{PbPb}}^{\text{TRENTo}}[w = 0.8 \text{ fm}] = \mathbf{833 \pm 4 \text{ fm}^2}$$

- Some reasons that  $\sigma_{AA}$  is not used as a constraint in analysis before:
  - $pp$  and nuclear inelastic cross-section have large uncertainty.
  - No exact match of geometry model to the experimental minimum-bias trigger.
  - Different IC models have different minimum-bias criteria ...
- Can we make use of the precision measurement cross sections in isobar collisions?

# Isobar double ratios

Larger difference at

1. large rapidity  $\rightarrow$  valance region.
2. peripheral (the skin) collisions  $\rightarrow$  significantly lower  $NN$  luminosity.

\*Nuclear PDF uncertainty not shown.
